

1 **Supplemental Material**

2           The primary purpose of this supplement is to provide further, more detailed justification  
3 of the four indices chosen for the classification tree presented in the full manuscript.

4           Figure 1 demonstrates the superior descriptive capacity of the tree with all four indices  
5 included as compared with the tree that is created from the exclusion from each of the four  
6 variables. Four separate trees are created (each uses a different combination of three of the four  
7 indices), and the variance at each level of the tree is measured. When these results are compared  
8 with the decrease in variance by employing all four indices, it is clear that none of these four  
9 indices can be removed without a substantial loss of descriptive power.

10           Figures 2 through 5 present groups of regime curve images in which three of the four  
11 indices are very similar, but yet the holistic nature of the catchments differ dramatically, thus  
12 verifying the importance of the one index that differs.

13           The two catchments in figures 2a. and 2b. are very similar in terms of aridity index, and  
14 their peak days for rainfall/runoff. However, the mountainous catchment in Montana (2a.)  
15 receives precipitation quite evenly throughout the year, while the Midwestern catchment in Iowa  
16 (2b.) receives more rainfall during summer months. The winter precipitation in Montana forms  
17 snowpacks, leading to peak runoff in the form of melt water in early June. The catchment in  
18 Iowa sees its runoff maximized during the same week as well – but the driver is rainfall, not  
19 melting. This distinction is nicely distinguished by the variable “seasonality,” yet thoroughly  
20 missed by the other three variables.

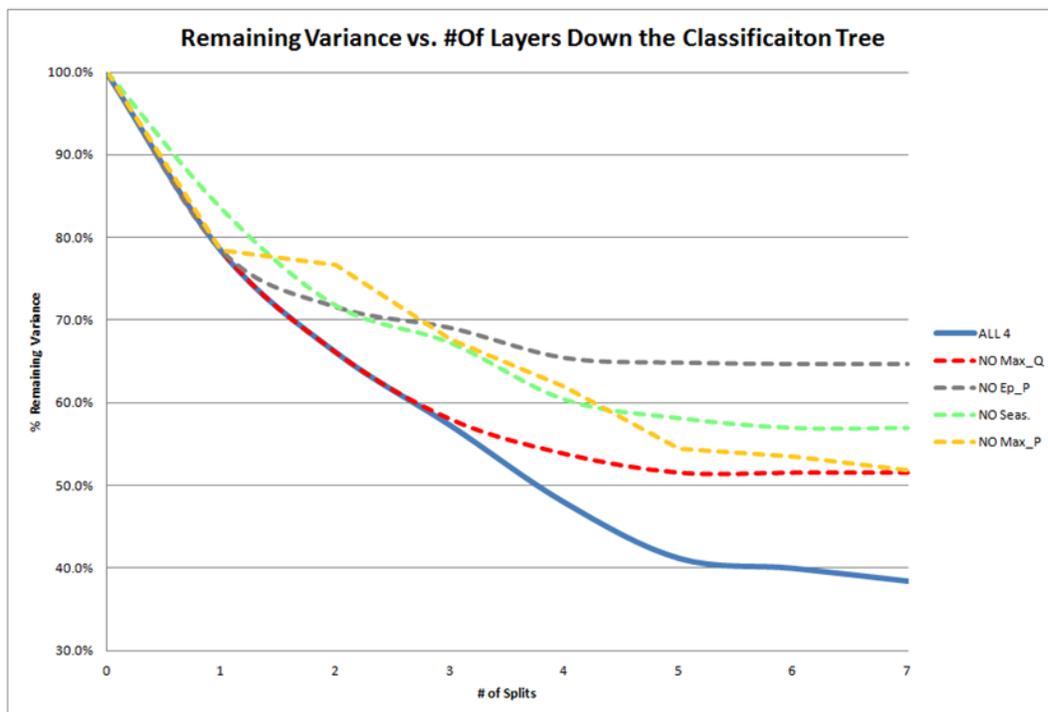

21           The catchments in figures 3a through 3c are virtually identical in terms of seasonality, as  
22 none of them display a strong seasonal signature for rainfall apart from a slightly higher quantity  
23 of winter precipitation. All three catchments display peak rainfall within essentially one week in  
24 early January and peak runoff within the same week of late-May/early-June. Without knowledge  
25 of aridity, these catchments would almost certainly fall within the same class. However, in  
26 looking at the catchment in 3c., the quantity of melt-driven runoff is nearly a full order of  
27 magnitude larger than the catchment in 3a. The difference is nicely explained by the substantial  
28 differences in aridity index.

29 The catchments in figures 4a and 4b display a very similar quantity of seasonality with  
 30 respect to precipitation, comparable aridity, and peak runoff during the same week. However,  
 31 these catchments are distinguished by the fact that the catchment in 4a receives its precipitation  
 32 during winter, out-of-phase with respect to PE, and thus, accumulates snow which exits as  
 33 melting snow months later. The catchment in 4b, because its precipitation pattern peak is shifted  
 34 almost exactly ½ year from the catchment on the left, receives precipitation in-phase with PE,  
 35 and produces, despite the similar timing, dramatically less runoff.

36 The catchments in figures 5a and 5b are both located in Washington. Both present  
 37 significant seasonality, extremely humid climates, and seasonal precipitation that arrives out-of-  
 38 phase with PE, peaking on the very same day in late November. However, these two catchments  
 39 present distinctly different climates as one emits maximum runoff in December (5a) and the  
 40 other peaks in June (5b). This implies a differing mechanism of runoff – 5a receives runoff from  
 41 winter rainfall that exits immediately (low residence time), shown by the Q regime curve  
 42 mirroring the P regime curve, while 5b produces runoff from winter rainfall and even more  
 43 notably from spring melt, thus producing a Q regime curve that does not follow P.

44 **Supplemental Figures**

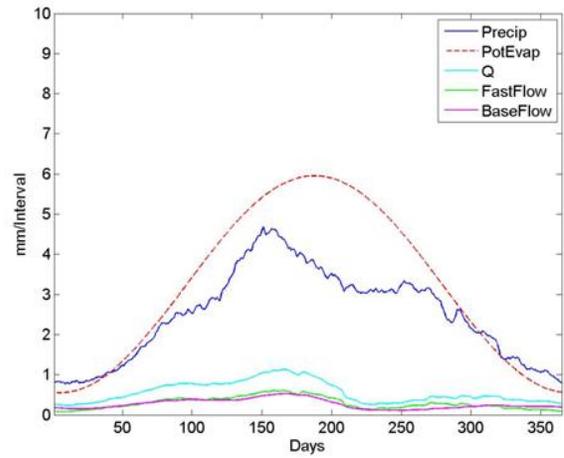

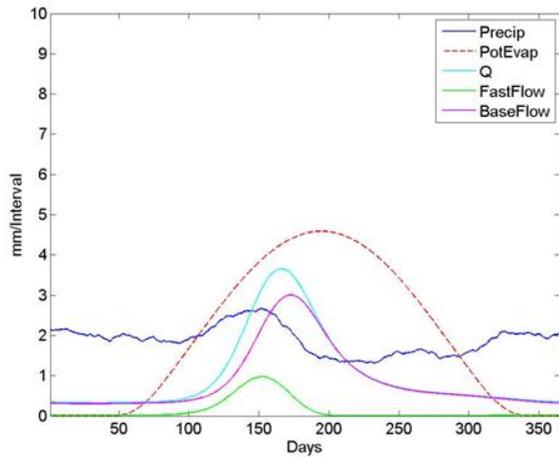

45 Figure 1: Decreasing entropy down the tree –performance with each variable removed

47 Figures 2a. and 2b: Different seasonality measurements

48 (Left) #203, Montana –  $Ep/P \sim 1.1$ ,  $MaxDayP = 152$ ,  $MaxDayQ = 165 \dots$  Seasonality  $\sim 0.15$

49 (Right) #91, Iowa –  $Ep/P \sim 1.3$ ,  $MaxDayP = 151$ ,  $MaxDayQ = 166 \dots$  Seasonality  $\sim 0.39$

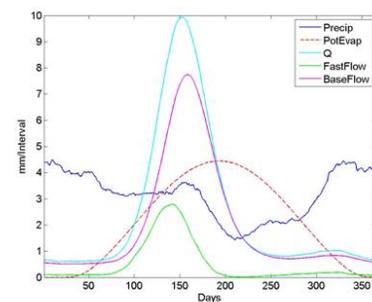

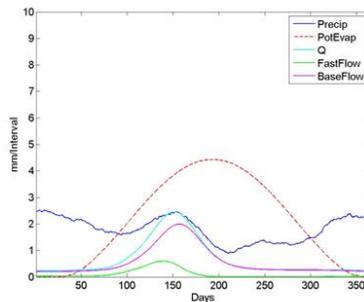

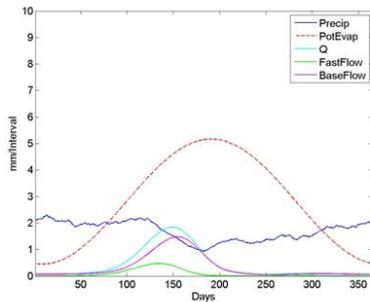

50

51 Figures 3a. , 3b. , and 3c: Different aridity indices

52 (Left) #243, Colorado – Seasonality  $\sim 0.19$ ,  $MaxDayP = 13$ ,  $MaxDayQ = 148 \dots Ep/P \sim 1.7$

53 (Center) #300, Montana – Seasonality  $\sim 0.23$ ,  $MaxDayP = 5$ ,  $MaxDayQ = 151 \dots Ep/P \sim 1.2$

54 (Right) #342, Montana – Seasonality  $\sim 0.23$ ,  $MaxDayP = 10$ ,  $MaxDayQ = 153 \dots Ep/P \sim 0.7$

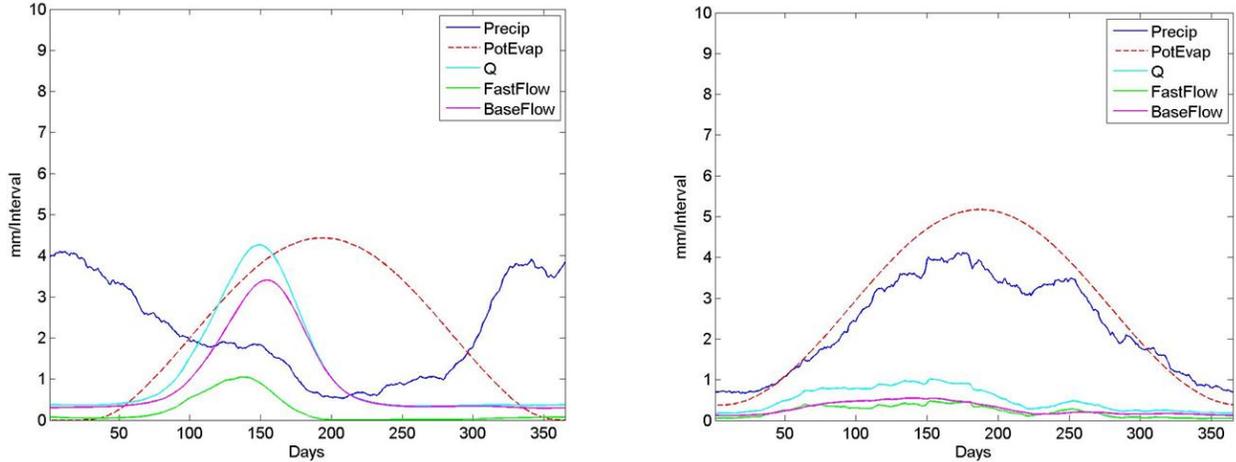

55

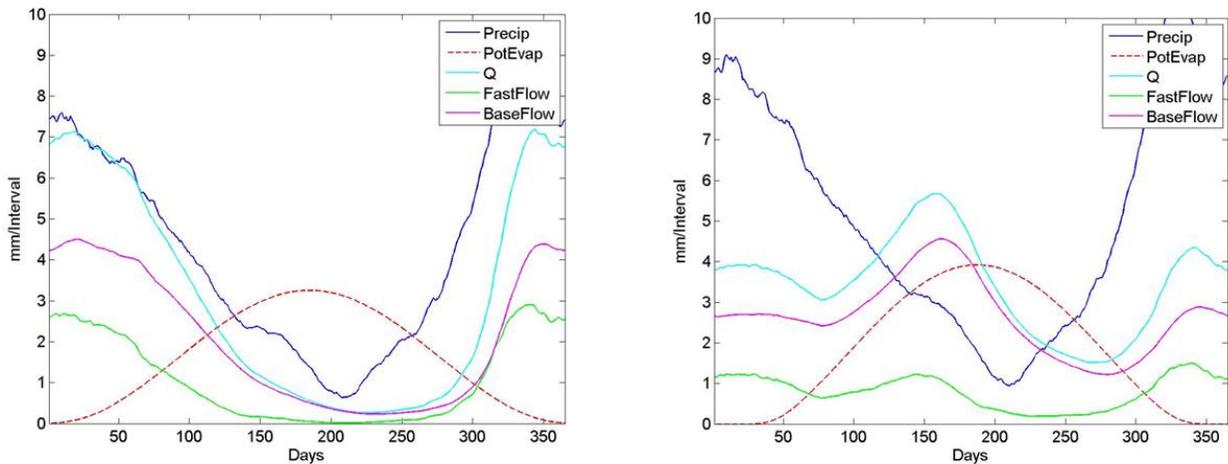

56

57

58 Figures 4a. and 4b: Different day of peak precipitation  
 59 (Left) #162, Idaho – Seasonality  $\sim 0.48$ ,  $Ep/P \sim 1.0$ ,  $MaxDayQ = 149 \dots MaxDayP = 8$   
 60 (Right) #388, Iowa – Seasonality  $\sim 0.45$ ,  $Ep/P \sim 1.2$ ,  $MaxDayQ = 152 \dots MaxDayP = 175$

61  
 62 Figures 5a. and 5b: Different day of maximum streamflow  
 63 (Left) #346, Washington – Seasonality  $\sim 0.52$ ,  $Ep/P \sim 0.38$ ,  $MaxDayP = 330 \dots MaxDayQ = 344$   
 64 (Left) #392, Washington – Seasonality  $\sim 0.49$ ,  $Ep/P \sim 0.35$ ,  $MaxDayP = 330 \dots MaxDayQ = 159$
