Table S1. List of GCMs from the CMIP6 experiment used in this study together with time periods SSP2-45 and SSP5-85 simulations of the GCM reach 1.5 to 4.0 °C global warming level (GWL) above the preindustrial period 1850-1900. GWL calculations are performed with respect to 1995-2014 by considering 0.85 °C warming between 1850-1900 to 1995-2014. NA means that the GCM simulation do not reach the specified GWL by the end of the simulation.

Figure S1. Observed vs. simulated SWE from CWatM and VIC models for three stations with highest numbers of observations.

a) Annual baseflow and runoff

b) Monthly baseflow and runoff from VIC

c) Monthly baseflow and runoff from CWatM

Figure S2. Sample annual and monthly runoff distribution obtained from CanESM5 GCM driven VIC and CWatM runs for historical (1971-2000) and 1.5 to 4.0 °C GWLs. The upper and lower portions of the bar plots show surface runoff and baseflow, respectively.

Figure S3: Flood frequency plots of annual maximum flows obtained from the model simulations driven by the GCM ensembles: a) VIC for Liard-M station, b) CWatM for Liard-M station, c) VIC for Liard-UC station, and d) CWatM for Liard-UC station. The results are shown for the historical period (1971-2000) and 1.5 and 3.0 °C GWLs. Dashed lines show the 95% confidence intervals. The years on the right axes of each plot indicate the two highest recorded historical flood events.
