1 SUPPLEMENTARY INFORMATION

2 We installed additional piezometer nests at 45 m distance from the ditch and 30 m 3 distance from the transect to obtain information based on hydrologic triangles. In general, 4 identified groundwater flow patterns were supported by these piezometer nests. At 45 m 5 distance from the ditch at the bog side, hydraulic heads indicated a prevailing lateral flow 6 pattern combined with a vertical component alternating between upward and downward 7 gradients down to 2.0 m depth. Hydraulic potentials in 3.0 m depth were > 20 cm lower 8 than in 2.0 m depth. This indicated a downward orientated flow in deeper catotelm peat 9 (Fig. S 1) which is coherent with modelled hydraulic potentials using the MODFLOW 10 model as described in the paper. In the same distance from the ditch under forest the 11 hydraulic heads remained upward directed throughout the study period (Fig. S 2).

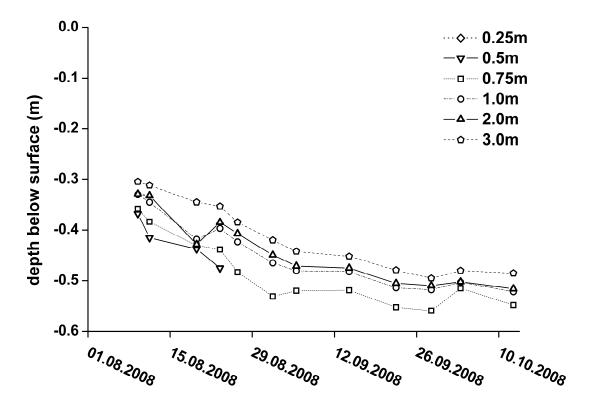

As a reference site, we installed an additional piezometer nest at a distance of 600 m from the ditch to monitor hydraulic heads at a pristine part of the bog, which can thus be assumed to be unaffected by drainage. Maximum water table fluctuations of 6.1 cm were rather small and similar to manual measured fluctuations of 6.3 cm at the 200 m site (data not shown). Hydraulic heads at the 600 m site were dominated by lateral flow with a discharging vertical flow component until the end of August and slightly downward orientated flow established in the beginning of September (Fig. S 3).
