Abstract

The bathymetric survey of Lake Vrana included a wide range of activities that were performed in several different stages, in accordance with the standards set by the International Hydrographic Organization. The survey was conducted using an integrated measuring system which consisted of three main parts: a single-beam sonar *Hydrostar 4300*, GPS devices *Ashtech Promark 500* – base, and a *Thales Z-Max* – rover. A total of 12 851 points were gathered.

In order to find continuous surfaces necessary for analysing the morphology of the bed of Lake Vrana, it was necessary to approximate values in certain areas that were not directly measured, by using an appropriate interpolation method. The main aims of this research were as follows: a) to compare the efficiency of 14 different interpolation methods and discover the most appropriate interpolators for the development of a raster model; b) to calculate the surface area and volume of Lake Vrana, and c) to compare the differences in calculations between separate raster models. The best deterministic method of interpolation was RBF multiquadratic, and the best geostatistical ordinary cokriging. The mean quadratic error in both methods measured less than 0.3 metres.

Comment [a2]: Now we exactly compare 14 interpolation method

Comment [a3]: We reduced number of aims.

The quality of the interpolation methods was analysed in 2 phases. The first phase used only points gathered by bathymetric measurement, while the second phase also included points gathered by photogrammetric restitution.

The first bathymetric map of Lake Vrana in Croatia was produced, as well as scenarios of minimum and maximum water levels. The calculation also included the percentage of flooded areas and cadastre plots in the case of a 2-metre increase in the water level. The research

1 presented new scientific and methodological data related to the bathymetric features, surface
2 area and volume of Lake Vrana.

3 **Keywords:** bathymetric survey, single beam sonar, interpolation methods, RTK-GPS, Lake
4 Vrana

6 **1 Introduction**

7 The methodology of bathymetric research has undergone many conceptual changes in the last
8 few decades, especially since the mid 20th century and the appearance of the single-beam echo
9 sounder. Rapid advances continued with the development of multi-beam sounders and laser
10 systems (airborne laser sounding systems) which can gather high-density data samples and
11 enable the development of a realistic underwater bottom model (Finkl et al., 2004; Ersten et
12 al., 2006).

13 The process of hydrographic measurement includes measurement and researching the
14 configuration of the bottom of an ocean, sea, river, lake or any other water-related object on
15 Earth (NOAA, 1976). The main goal of most such hydrographic research is to gain the exact
16 data necessary to develop nautical charts featuring special details of types of navigational
17 hazards. Other goals include gaining information crucial to the management and protection of
18 coastal areas, exploitation of resources, scientific practices, national spatial data
19 infrastructure, tourism purposes etc. (IHO, 2005). Contemporary bathymetry, as a field within
20 hydrography, is the science of measuring depths and determining the physical properties of
21 the underwater bottom on the basis of analysing data gained from recorded profiles. There are
22 several different methods and techniques of bathymetric measurement, which depend on the
23 complexity of the project (its final purpose, and the size of the area under research). The
24 success of bathymetric measurement depends mostly on a detailed planning process, which in
25 turn enables the organization and tracking of the measurement process from start to finish
26 (IHO, 2005). During this particular research, the measurement plan included a wide range of
27 activities and was performed in several phases according to the standards of the International
28 Hydrographic Organization. The area surveyed included the whole of Lake Vrana, with a total
29 surface area of 29.865 km² (Šiljeg, 2013). Lake Vrana is the largest, natural, freshwater lake
30 in the Republic of Croatia. This cryptodepression is an ecologically sensitive area, located in
31 the Mediterranean part of Croatia (Zadar County) (Romić et al., 2003). The lake is an
32 important economic resource for the local community, but also provides a natural habitat for

1 many bird species (Šikić et al., 2013). The Lake Vrana is complex body, which also affected
2 the bathymetric survey.

3 Since the terrain formations in the natural environment feature a high level of complexity,
4 most scientists opt for research via the development and analysis of digital elevation models
5 (Dikau et al., 1995; Bishop and Shroder, 2000; Millaresis and Argialas, 2000; Wilson and
6 Gallant, 2000; Tucker et al., 2001; Shary et al., 2002; Chaplot et al., 2006; Wilson, 2011).
7 Today, most of the data gathered is point-related, regardless of rapid developments in
8 technology. This means that the data collected features specific values for a certain variable
9 only for specific x and y coordinates. In order to find continuous surfaces, which are
10 necessary for the process of research and understanding of our environment, some values
11 need to be approximated for spaces which are not measured directly. This is done using
12 various methods of interpolation (Collins and Bolstad, 1996; Hartkamp et al., 1999; Hu et al.,
13 2004; Naoum et al., 2004; Li and Heap, 2008, Erdogan, 2009). The final result in the
14 interpolation method is the model that approximates or simplifies the Earth's surface. Each
15 method produces a different result, so the main challenge is to determine the characteristics of
16 errors and variability of approximated values by comparing and testing different interpolation
17 methods.

18 The bathymetric survey of Lake Vrana was performed in order to enable optimal management
19 of the water level, to classify the lake's bottom, to create a model and bathymetric map, and to
20 enable better management and protection of the lake's flora, fauna etc. This process implies
21 all the hydro-technical measures and infrastructure that facilitate a deliberate change in water
22 distribution, which in turn enables the more efficient management of natural water resources,
23 protection from water hazards and prevention of water pollution. The water regime includes
24 the entire dynamics of constant change, both the quantitative and qualitative aspects of water,
25 and the dynamics between the water and surrounding area (Kuspilić, 2008). Inconsistent
26 management of the water regime has caused some extreme changes in the water level,
27 salinity, temperature, oxygen levels etc. As a result, the lake has been poorly exploited for
28 other purposes: tourism, water resource management, biodiversity, ecological activities etc.
29 This culminated in a series of negative consequences in 2012, when a record number of fish
30 died (URL 1).

31 An optimal water regime can only be achieved if the amount of water in the lake is known at
32 any moment, and if Prosika drainage canal has a regulatory water infrastructure, as well as an
33 efficient drainage ditch used to regulate the water level, depending on the season.

Comment [a4]: We added new text in introduction and reduced some parts.

1 The main aims of this research are as follows: 1) to compare the efficiency of 14 methods of
 2 interpolation and determine the most appropriate interpolators for the development of a raster
 3 model of the lake (on the basis of data gained by bathymetry and by using the cross-validation
 4 method); 2) to calculate the surface area and volume of the lake and to compare the results
 5 between the raster models; 3) to develop the first bathymetric map of Lake Vrana (Fig. 13)
 6 which will enable calculation of the percentage of flooded areas in the Nature Park and the
 7 flooded plots, in the case of a 2-metre rise in the water level. This will serve as tool for
 8 developing a scenario for future changes in water level.

Comment [a5]: Reduced number of aims. Now we have 3 main aims in research.

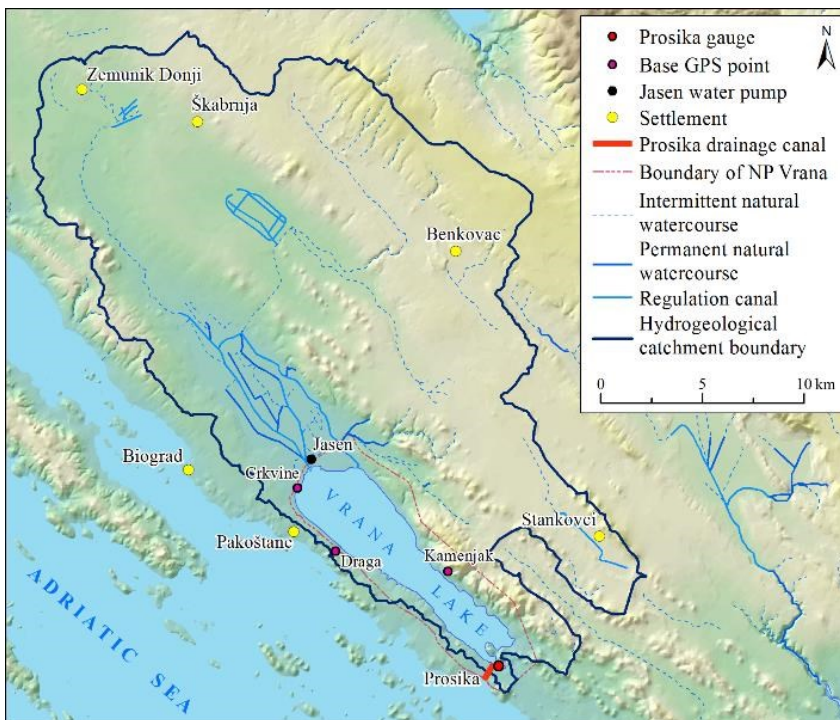

9

10 2 Study Area

11 Vrana Lake in Dalmatia is the largest natural lake in Croatia by surface 30.2 km², with the
 12 length of 13.6 km and width of 1.4 – 3.5 km (JUPPV, 2010). However, none of the written
 13 sources mention the process used to calculate the surface area, the water level included, what
 14 year, month, or methods and techniques used.

Comment [a6]: Added basic information about Vrana Lake

15

16

17

18 Figure 1. Study area with lake hydrogeological catchment

Comment [a7]: Added new map: Study area with lake hydrogeological catchment. We have marked all the place names mentioned in the text.

1 It is known that the surface area of the lake changes constantly and that it is conditioned by
2 the water level and shape of the surrounding terrain. In the period from 1948 to 2008, the
3 lowest water level was 12 cm (measured in reference to the Prosika gauge) or 0,03 meters
4 above sea level, measured in 1990 and 2008. The highest was 236 cm measured in reference
5 to the Prosika gauge (2.24 m a.s.l.), measured in 1974 and 1994. The mean value was 0.81 m
6 a.s.l. (JUPPVJ, 2010). The water level is influenced by major factors such as inflow, drainage
7 and evaporation, but also by complex hydrological and hydraulic effects such as water
8 balance, salt and fresh water content, sea tides and other factors influencing changes in sea
9 level (JUPPVJ, 2010).

Comment [a8]: We explained the difference in elevation between Prosika gauge and sea level.

10 The water system of Lake Vrana is complex, which affected the selection of methods for the
11 bathymetric survey. The area included Lake Vrana in its entirety, with a surface area of
12 29.865 km² (in relation to the water level of +0.42 m, measured in reference to the Prosika
13 gauge) (Šiljeg, 2013).

14 The lake is characterized by:

15 1) A high percentage of shallow water – over 65% of the lake's surface features a water depth
16 of -1.76 m, while the deepest is -3.73 m (in relation to the water level of +0.42 m, measured
17 in reference to the Prosika gauge or 0.3 m a.s.l.). Prosika gauge is located near Prosika
18 drainage canal which connect Vrana lake and Adriatic sea (Fig. 1). The canal (dimensions:
19 875 m length, 8 m width and 4-5 m depth) was dug through in 1770 to attain new agricultural
20 areas in Vrana field and protect them from seasonal floodings.

Comment [a9]: We explained what is Prosika drainage canal

21 2) Low vertical dissection – the absolute vertical difference over the entire area of the lake
22 bottom is only 3.46 m. More than 90% of the lake's bottom features a slope inclination of 2°

23 3) Low water transparency and high turbidity, especially during even the slightest winds

24 4) Lush vegetation (grass) on the lake's bottom and the surrounding shoreline
25 (*Phragmitetalia*)

26 5) Significant seasonal oscillations in the lake's water level

27 6) Coverage of parts of the lake's bottom by unconsolidate sediments

28 29 **3 Research Materials and Methods**

Comment [a10]: Changed the structure and reduced text.

30 **3.1 Plan for the Bathymetric Survey**

31 In order to perform a bathymetric survey, it is necessary to have a detailed plan, which
32 enables tracking research development and the organization of the research from start to

1 finish. The plan included a wide range of activities and was structured in a number of phases:
2 1) determining the exact research area, 2) determining the purpose of the bathymetric survey,
3 3) application of the survey method (techniques, accuracy, referential horizontal and vertical
4 geodesic system, equipment, etc.), 4) determining the time frame (short or long), 5) gathering
5 various secondary data (aerial photos, data from the cadastre, information on the water level,
6 salinity, temperature, etc.), 6) considering limiting factors (budget, logistics, etc.) and 7) data
7 processing (conversion, filtering, interpolation methods, etc.).
8

9 3.2 Equipment used

10 **Based on the characteristics of the lake**, some complex, more efficient techniques, such as
11 measuring using a multi-beam echo sonar, or laser sonar, would have been inappropriate,
12 considering the morphology of the bottom. The percentage of the recorded bottom would
13 increase greatly in relation to recordings from a single-beam sonar, but the cost of the survey
14 and amount of data acquired would significantly increase as well. After consideration, it was
15 clear that the most efficient solution was bathymetric measurement and the use of a single-
16 beam ultrasound device.

Comment [a11]: We added new text

17 **In order to avoid frontal waves (proposed by IHO, 2005)**, an inflatable *Hondawave* boat was
18 used (Fig. 2a). The boat was the optimal vehicle due to its small dimensions (3.85 m) and
19 economical engine, and because it was easy to install the surveying equipment on it.

20 The bathymetric measurement was performed using an integrated measuring system (Fig. 3)
21 **Installed equipment** included three main components: a *Hydrostar 4300* sonar, GPS devices
22 *Ashtech Promark 500* and a *Thales Z-Max*. These were connected via the RTK controller
23 *Juniper System-Allegro*, which enabled real-time connection and data registration in the
24 *FastSurvey* programme. This enabled recording of the sonar coordinates and corresponding
25 depth. The programme automatically recalculated the coordinates from the GPS into the local
26 projection coordinates. The selected projection was the universal transversal Mercator, Gauss-
27 Krüger shape with a central meridian of 15, a factor of scale change of 0.9999 and a false
28 easting of 5 500,000. The Bessel 1841 ellipsoid was used.

29 Two GPS devices were also used: a base or referential **device (Fig. 2b)**, which was positioned
30 according to precisely determined coordinates, and a **rover device (Fig. 2c)**, which was used
31 in the work area. A data-exchanging connection was established between them via a UHF
32 radio transmitter, which would also have been possible via various GSM devices.

Figure 2. (a) *Hondawave* inflatable boat with wooden support. (b) Base GPS and UHF antenna. (c) Rover GPS and dual-frequency probe

Comment [a12]: We merged old images 1, 2 and 3 in new Figure 2

6 The distance between the base and referential devices had to be determined in advance, in
7 order to achieve an adequate degree of precision. This was named the *base line* and its
8 maximum value was 50 kilometres. The distance between the base GPS and the UHF
9 transmitter had to be a minimum of 10 m.

Figure 3. Integrated measuring system – combination of GPS-RTK and a sonar

Since the UHF signal was rather weak throughout the lake, three base points were determined using the Ashtech Promark 500 and CROPOS system: 1) coordinates $\lambda=5\ 541\ 365.709$, $\varphi=4\ 865\ 017.188$ m – 2.02 m above sea level in the northeast section of the Nature Park (Crkvine), 2) coordinates $\lambda=5\ 543\ 197.353$, $\varphi=4\ 861\ 981.863$ m – 36.69 m above sea level in the western parts of the Nature Park (Draga), 3) coordinates $\lambda=5\ 548\ 694.214$, $\varphi=4\ 860\ 958.663$ m – 62 m above sea level in the eastern part of the Nature Park (Kamenjak) (Fig. 1). They were

1 connected by a benchmark and measuring gauge at the Prosika location. A base GPS device
 2 was set at those points, depending on the phase of the survey, and connected to a UHF
 3 transmitter (with all components) in order to achieve a connection (signal) with the mobile
 4 GPS installed on the inflatable boat.

5 A dual-frequency probe was fixed to this support with a rover GPS device submerged 20 cm
 6 below the water level (Fig. 2c). This arrangement was necessary due to the shallow water of
 7 the lake and low water level at the northwest end. Since the *Hydrostar 4300* sonar supports
 8 depth recording simultaneously at two frequencies, the survey was conducted at two
 9 frequencies: low – 30 kHz and high – 200 kHz.

10 The bathymetric survey was performed according to the previously established profiles, on a
 11 geo-referential cartographic surface (Croatian Base Map and digital orthophoto to the scale
 12 1:5000). The basic measuring profiles were planned perpendicular to the slope of the terrain,
 13 in a northeast-southwest direction. The planned profiles of the survey (basic bathymetric
 14 profiles) ensured good coverage and high resolution in the research area. The survey also
 15 included four transversal profiles which intersected with the main profiles, enabling the
 16 comparison and control of the measured depths.

17 Within the borders of the shoreline of Lake Vrana, 375 basic profiles were achieved. The
 18 distance between adjacent profiles was set at 200 metres, which corresponds to the desired
 19 mapping resolution to the scale 1:30 000.

20

21 3.3 Time Frame

22 The time frame, and the first day of the survey were determined by the water level. The water
 23 level is important since it is impossible to register a depth of more than 0.5 metres by

24 transducer. Weather conditions are important for
 25 navigation and the quality of data registration (Fig. 4).
 26 Wind, rain, waves and cold, for example, are usually
 27 limiting factors. Weather reports and water level
 28 oscillations were continuously observed from the
 29 production of preliminary plans in November 2010
 30 until the beginning of the survey.

32 Figure 4. The effect of frontal (a) and dorsal (b) waves on data registration (Clarke, 2003).

1 The measurement process was conducted in two phases (Fig. 5): 1) from 10-12 May 2012,
2 and 2) from 7-9 June 2012.

3 The first phase took two days, and included a survey of 14.351 km² of the northern part of
4 Lake Vrana. The total length of the measured profiles was 71.3 km, and the total amount of
5 points gathered was 5643. In the first phase of investigation the water level measured at the
6 Prosika station was 0.42 m. The limiting factors for the survey in this part of the lake were the
7 dense grassy vegetation on the bottom, the shallow water and the lush surface-level vegetation
8 which hindered navigation. Measurement was cancelled in these parts, based on previously
9 established profiles, while the shallow water was measured using a plumb-line. As a result,
10 this survey cannot be classified as systematic. It is nevertheless very important in relation to
11 the part of the lake that was measured, since the terrain there is flat or minimally inclined. An
12 acceptable level of interpolation is possible in areas featuring an irregular layout of profiles.

13 The second phase featured negligible limiting factors, so the survey was conducted according
14 to plan. The water level at the Prosika station was 0.37 m. A total area of 15.514 km² was
15 surveyed in the southern part of the lake. The total length of the measured profiles was 82.5
16 km, and the total amount of points gathered was 7208.

17
18

19 Figure 5. The phases and plan of the bathymetric survey

20

1 **3.4 Processing the Bathymetric Data**

2 The data obtained from measurement was transferred to a PC via the *Juniper System-Allegro*
3 controller and the *Fast Survey* programme package for further processing and interpolation.
4 During measurement, the controller creates a separate file with information regarding the
5 point coordinates, time obtained, and depth recorded. Data processing included filtering out
6 noise, calibrating the checked depths to a common referential level, and interpolation. The
7 filtering process was implemented according to a programme which enabled the removal of
8 errors in the data registry (Fabulić, 2012). Records of water depth were calibrated in relation
9 to the Prosika benchmark and measuring gauge.

10 Since parts of Lake Vrana are quite difficult to survey, measurements taken by ultrasound
11 showed some background noise. In simple terms, the ultrasound beam bounces off the first
12 obstacle it encounters, so the echo sounder calculates the distance to that obstacle and
13 represents it as a depth measurement. However, such obstacles are not always on the bottom
14 of the lake, and indeed, random noise may be generated by floating matter, plankton, fish, or
15 vegetation (Pribičević et al., 2007). These sounds need to be filtered and reduced in order to
16 obtain correct, usable data. An additional caution is necessary when filtering such data. Low
17 frequencies (30 kHz) cannot penetrate the dense, complex, “sedimentary” vegetation which
18 forms the new bottom. As a result, low frequency measurement did not yield adequate results,
19 since it could not properly determine the density of the silt or vegetation, or the boundary
20 between the rocky and muddy bottom. Therefore it was used only during the first day of the
21 survey. Another deficiency recorded using the low frequency was significant leaps in profiles,
22 especially in places where the frequency penetrated the vegetation and muddy deposits. This
23 also indicated significant differences in the levels of muddy deposits. In order to perform a
24 more detailed analysis, a sediment profiler should be used, featuring a frequency of up to 15
25 kHz, which could be used to gain detailed information regarding the lake’s bottom (Lafferty
26 et al., 2005; Pribičević et al., 2007). Since the lake is shallow, and water transparency during
27 the survey was relatively good, it was relatively easy to determine the features of the lake’s
28 bottom and differentiate vegetated from non-vegetated areas.

29

30 **3.5 Interpolation Methods**

31 In this research, the most appropriate methods have been chosen, based on eight statistical
32 parameters: minimum value, maximum value, range, sum value, mean value, variance and

Comment [a13]: We added new chapter about interpolation methods

1 standard deviation. Of these, standard deviation, or mean quadratic error, is especially worth
2 mentioning, since it is the most used method world-wide for determining the precision of
3 digital elevation models (Yang and Hodler, 2000; Aguilar et al., 2005). In addition to
4 analyzing parameters, interpolation methods were compared on the basis of high-fidelity,
5 two-dimensional and three-dimensional graphic representations of data sets. Volume
6 comparison methods were also used, by employing various algorithms, as well as methods for
7 calculating and comparing profiles (Pribičević et al., 2007; Medved et al., 2010).

8 In order to compare the accuracy of the interpolation methods, the method of cross-validation
9 was used. Most authors suggest using this method in order to achieve a successful evaluation
10 of accuracy (Cressie, 1993; Smith et al., 2003; Webster and Oliver, 2007; Hofierka et al.,
11 2007). The main aims of this research were as follows: to compare the efficiency of 14
12 different interpolation methods and discover the most appropriate interpolators for the
13 development of a raster model

14 The fourteen interpolation methods were used as follows (with abbreviations):

15 Deterministic methods: Inverse distance weighting (IDW), Local polynomial function (LP),
16 RBF (radial basis function) - Completely regularized spline (CRS), RBF - Spline with tension
17 (SWT), RBF - Multiquadric function (MQ) and RBF - Inverse multiquadric (IMQ).

18 Geostatistical methods: Ordinary kriging (OK), Simple kriging (SK), Universal kriging
19 (UK), Disjunctive kriging (DK), Ordinary cokriging (OCK), Simple cokriging (SCK),
20 Universal cokriging (UCK) and Disjunctive cokriging (DCK).

21 22 **3 Research Results**

23 **3.1 Interpolation of data gathered from the bathymetric survey**

24 In order to generate continuous areas necessary for research and knowledge of the bottom of
25 Lake Vrana, it was necessary to approximate values in areas that were not sampled directly.
26 This was done using various interpolation methods.

27 The main aims of this part are as follows:

- 28 1. To compare the effectiveness of fourteen interpolation methods
- 29 2. To determine the most appropriate interpolators for the purpose of developing a raster
30 model of the lake, on the basis of bathymetric data, by using the cross-validation method
- 31 3. To calculate the surface area and volume of the lake, and to compare differences in the
32 calculation between raster models.

1 The effectiveness (quality) of interpolation methods was analyzed in two phases. In the first
 2 phase, 12 851 points were used to develop a model of the lake and compare interpolation
 3 methods. The second phase covered 30 233 points. Using the *ArcGIS* extension within the
 4 *Geostatistical Analyst* programme, interpolation parameters were automatically optimized for
 5 each interpolation methods (Table 1).

6 Four parameters influenced the quality of the output deterministic methods results: distance
 7 exponent, number of neighbours, distance, and number of sectors. The number of neighbours
 8 which influenced an approximated point was set at 15. The criteria for distance used a circular
 9 search zone with a defined distance radius. All methods, except local polynomial methods,
 10 featured a radius of 3619.9 m (Table 1).

3
 4 The first phase showed that all the used methods of interpolation showed satisfying results,
 5 and were adequate for developing digital elevation models of the lake, since they had similar
 6 parameter values (Table 2). The main reason for this is the slight difference in depth values,
 7 low vertical dissection of the lake's bottom and minimal percentage of elements with sudden
 8 leaps in height. The range of value for standard deviation, considering the automatically
 9 optimized parameters, was between 0.197 and 0.249 m. According to all parameters, the best
 10 method was simple cokriging (0.197 m). The reasons for that were the principle of the
 11 method's process (μ = known stationary mean value, taken as a constant for the entire
 12 research area and calculated from the median data value) and the maximum range between the
 13 depth values (only -3.46 m). The mean value for the entire area was -1.763 m.

14 Since most authors point out that the quality of stochastic methods depend on the choice of
 15 criteria regarding semi-variograms, a comparison was made between the criteria automatically
 16 determined by software and those manually determined for the ordinary cokriging method.
 17 The two most common theoretical models were tested: spherical and Gauss (Table 3). The
 18 purpose of manually assigning criteria is to find out the minimum deviation and minimum
 19 value for standard deviation. In the case of the spherical model, the minimum value of
 20 standard deviation was the distance of 1800 metres (0.221 m). Unlike the automated software

1 process, finding the minimum value of standard deviation manually is more difficult and
 2 time-consuming (it requires inputting the parameters of interpolation repeatedly until the
 3 minimum value is found).

4 Table 3 shows that the output results regarding the standard deviation do not reveal significant
 5 differences. For example, the difference between automatic and manually found standard
 6 deviation in the case of the spherical model for 12 851 points is 0.011 m. However, it is
 7 notable that the maximum error in the approximation for the same model is 0.208 metres
 8 greater (2.238).

9

10 Table 3. Comparison of manually and automatically determined parameters of the
 11 interpolation method (example for OCK).

Model	Range	Sill	Nugget	Lags	Distance	NL*	NB*	SD*	MPE*
Spherical (CAD*)	8496.4	0.591	0.227	886.11	10 633.32	12	4	0.232	2.030
Spherical (MD*)	1777.9	0.418	0.027	150.00	1800.00	12	4	0.221	2.238
Spherical (CAD*)	6337.5	0.477	0.302	886.11	10 633.32	12	4	0.238	1.948
Gauss (MD*)	133.8	0.042	0.048	20.00	240.00	12	4	0.220	2.235

12 *IM – interpolation method, NL – number of lags, NS – number of sectors, SD – standard deviation, MPP –
 13 maximum prediction error, CAD – criteria automatically determined, MD – manually determined

14

15 According to Malvić (2008), a decrease in distance also decreases the deviation, since the
 16 values of closer points are more similar than the values of more distant ones. The decrease in
 17 deviation should decrease the standard deviation calculated from the differences in the
 18 measured and the approximated values. However, the quality of approximation in other parts
 19 of the model might be questioned. By testing using ordinary kriging, the conclusion was that
 20 the decrease in distance affected the standard deviation positively, and negatively in areas that
 21 were not included in the direct measurement. The values obtained in such areas greatly
 22 surpassed the values of the surrounding measured points. For example, a semi-variogram for
 23 Lake Vrana was made, which was used to compare 30 233 points. The determined distance
 24 was 1200 m, and the standard deviation for 12 851 points was 0.298 m. For the distance of 12
 25 000 m, the standard deviation was 0.471 m. In the case of the first distance (1200 metres) the
 26 lowest value of depth for the entire model was -5.21 m (the lowest measured depth was -3.73
 27 m). As much as 0.246 km² of the model's surface fell within the category of -3.73 m to -5.21
 28 m (Fig. 6). This result implies a serious error that would create an increase in the volume of
 29 the lake. The second distance (12 000 m) did not feature any values above -3.578 m. This

example shows that standard deviation can be an unreliable parameter when taking the values of the entire model into account.

Figure 6. Areas that were not directly measured during the survey (red squares)

8 Points gathered by the bathymetric survey did not include the entire surface of the lake, since
 9 the echo sounder could not gather data in areas above -0.5 m . Since that resulted in a lack of
 10 data at the edges of the lake, the modeling toolset poorly extrapolated the surfaces (Fig. 6).

11 Visually compared, the methods generally show the greatest differences in the smoothness of
 12 isobaths, which is logical since the differences between the chosen parameters are essentially
 13 negligible. A more detailed analysis indicates the results of certain methods (appearance of
 14 continuous surfaces at micro levels).

15 In order to develop a digital model of the lake that would enable various simulations, such as
 16 changes in the water level, it is necessary to consider the data that refers to the surrounding
 17 terrain (height data, gathered by aero-photogrammetry). The combination of precisely
 18 obtained data on heights and depths enables the interpolation for the areas that were not
 19 directly included in the survey. The output results turned out well, since the lake features
 20 mostly low, flattened shores.

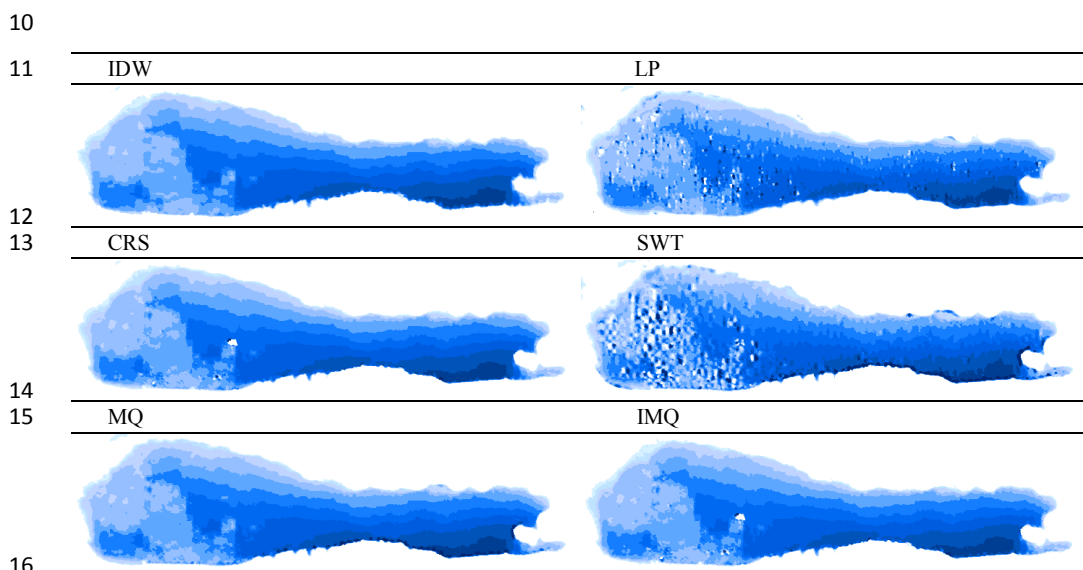

21 Due to curious output results in the first phase, the comparison of methods of interpolation
 22 was repeated for 30 233 points within the Lake Vrana Nature Park (Table 4). Of those points,
 23 12 851 were depths (bathymetrically measured points), and 17 832 were elevations (points
 24 with x, y and z values gathered by aero-photogrammetry). Statistic indicators were calculated
 25 only for the bathymetrically gathered points. The output results were quite different. The use
 26 of elevation points, which are necessary to develop a good digital elevation model of the lake
 27 and its surroundings, showed numerous deficiencies in most of the interpolation methods,
 28 clearly visible in Table 4 and Figure 7.

29

3
 4 Ordinary cokriging turned out to be the best method of interpolation according to all relevant
 5 parameters (Table 4, Fig. 13). Figure 7 clearly shows the characteristic of the simple kriging
 6 method, when the range of elevation is 307.23 metres, in which case the mean value for the
 7 entire area is 38.02 m. Along with the ordinary cokriging method, satisfactory results were
 8 obtained from the inverse distance weighting method, RBF – multiquadratic and ordinary
 9 kriging. The standard deviation according to all three methods was less than 0.5 m.

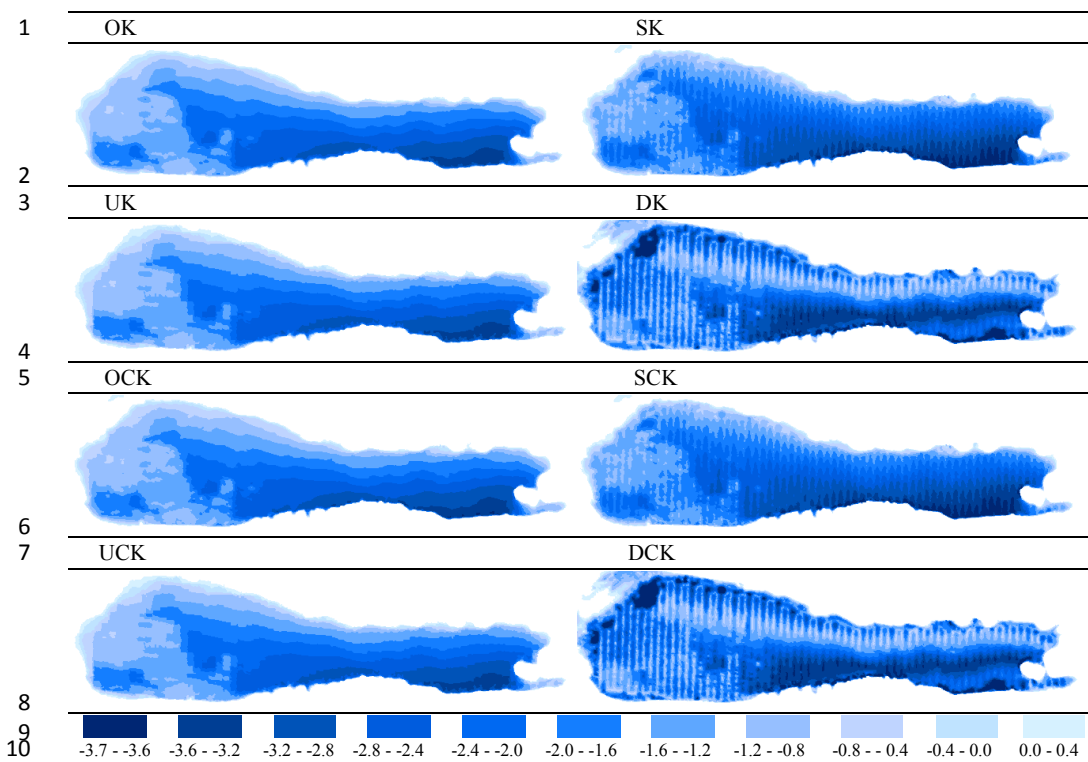

Figure 7. Digital elevation models generated from surveyed data (difference between deterministic and geostatistical interpolation methods)

Comment [a16]: Changed name of figure

The differences between the four best methods of interpolation are obvious in the two-dimensional (Fig. 10) and three-dimensional graphic representations. Figures 8a and 8b show the more vertically dissected part of the lake, with an AB profile, and a length of 1500 m, which was used as a further testing sample for the four best interpolation methods. The profile line was drawn so as to cover 6 bathymetrically measured points.

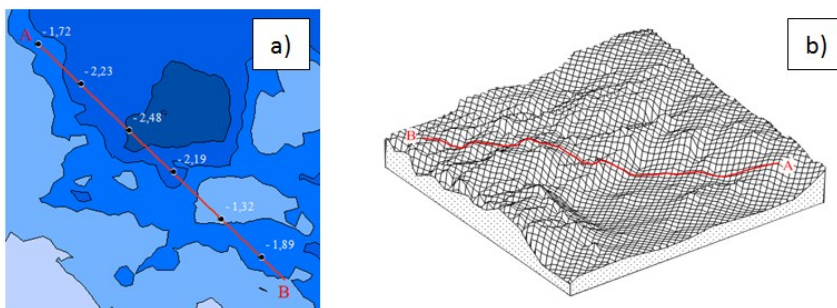

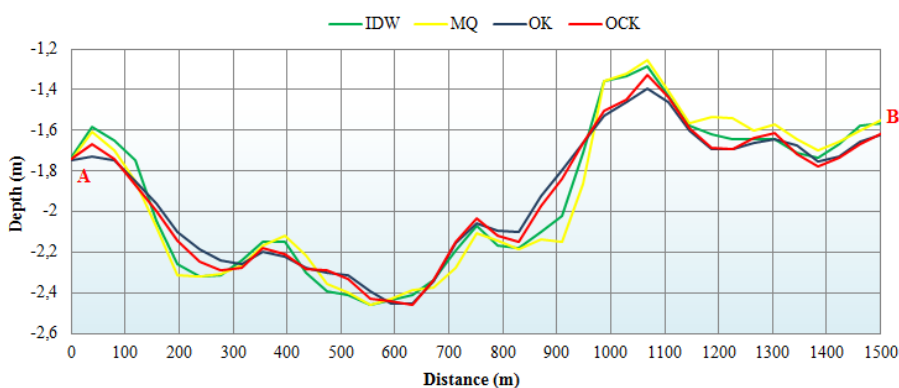

Figure 8. (a) Profile display, contour map. **(b)** Profile display, three-dimensional model

1 After drawing the profile line, it was necessary to calculate the intersection for the defined
2 profiles based on the regular network generated by the interpolation, i.e. to convert the two-
3 dimensional profiles into 3D lines which feature x, y and z values.

4

5

6

7 Figure 9. Differences in profile for the four best interpolation methods

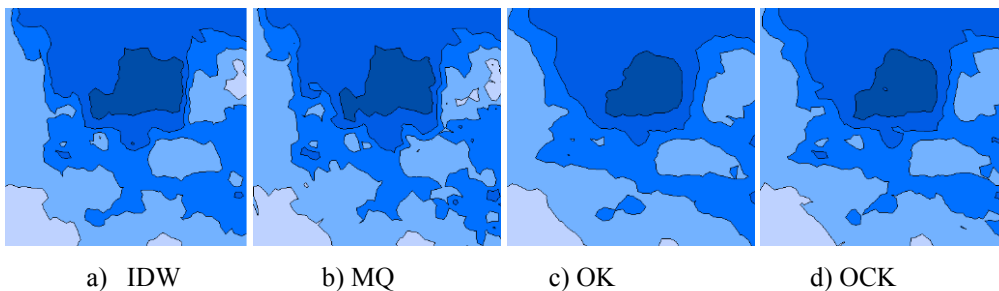

8

9 This approach enabled comparison of the profiles, a clear representation of the interpolated
10 lake's bottom and the detection of deviation between the bathymetrically measured points and
11 those approximated by the model. Figure 9 shows a difference in the interpolation method of
12 deterministic (inverse distance weighting, RBF – multiquadratic) and geostatistical methods
13 (ordinary kriging, ordinary cokriging).

14 The final result of comparing methods of interpolation using *ArcGIS* expansion *Geostatistical*
15 *Analyst* is to obtain a regular spatial network or grid. Usually, the greatest problem is deciding
16 between greater spatial resolution or pixel size (Hengel, 2006). In this case, the software
17 optimized the pixel size at 40 metres. The spatial resolution corresponds to McCullagh's
18 (1988) method of determining pixel size. The size was calculated using a grid calculator and
19 the method of point sample analysis (Hengel, 2006). On the basis of 12 851 points and an area
20 of 29.865 km², a spatial resolution of 24.2 m was generated. This method (McCullagh, 1988)
21 was not chosen due to a disproportionate ratio between the distance of the profiles and the
22 points measured in them. Due to the high density of the sampling within a profile (10 m), but
23 also due to variability in the elevation of the neighboring points, a problem known as the
24 "Prussian helmet" occurs (Šiljeg, 2013). The grid was later used as input data for the purpose

1 of developing a three-dimensional representation. In addition, it can be used to develop
2 various maps to show contours, lake terrain, grid models, slope, etc.

3

7 Figure 10. Representation of contours in part of the lake (difference between interpolation
8 methods)

9

10 **3.2 Surface area and volume of the lake**

Comment [a17]: We reduced the text

11 The final phase of bathymetric research involved calculating the lake's surface area and
12 volume (Diolaiuti et al., 2005; Ahmed, 2010). The output results of a certain analysis depend
13 on the method of data gathering, dissection of the lake bottom of the lake density and
14 distribution of points, spatial resolution (pixel size), algorithms and the interpolation method
15 used.

16 The volume of a lake can be efficiently calculated by a regular grid obtained by using a
17 certain interpolation method. The calculation process was relatively simple, since the number
18 of pixels was known (18 714), as well as the surface (40 m x 40 m = 1600 m²) and the height
19 (z) within the coordinate system. A pixel in this case represents a three-dimensional object
20 (cube or a quadratic prism) based on which the volume can be calculated.

21 In order to compare it with other algorithms, the volume was calculated for the regular spatial
22 grid, obtained by the ordinary cokriging interpolation method. The volume amounted to 49
23 783 536 m³. This method yielded good results, since the difference between the result and the
24 arithmetic mean for three rules (trapezoidal, Simpson's and Simpson's 3/8) was 293 143 m³
25 (Table 5). The output results of volume calculation depend primarily on the spatial resolution;
26 the lower the resolution, the more precise the calculation, because the leaps in values between
27 pixels become less.

1 In order to calculate the volume, three more complex Newton-Cotes formulae were used: 1)
 2 the extended trapezoidal rule, 2) the extended Simpson's 1/3 rule and 3) the extended
 3 Simpson's 3/8 rule (Press et al., 1988). Newton-Cotes formulae are very useful and provide a
 4 direct technique for approximately calculating an integral by numerical methods and
 5 algorithms (their use results in various degrees of errors in the final calculation) (Medved et
 6 al., 2010). They are used to calculate the surface area and volume of various shapes.
 7 Simpson's rule approximates an integral by the Lagrange polynomial which passes through
 8 three points, while the trapezoidal rule approximates by the Lagrange polynomial passing
 9 through two points (Palata, 2003).

10

11 **Table 5. Volume, surface and perimeter of Lake Vrana at 0.4 metre water level in reference to**

13

14 Table 5 shows calculated values for the volume derived from Newton-Cotes formulae,
 15 applied to five different methods of interpolation. Since every method displays a certain level
 16 of error in the approximation of the volume, arithmetical means for the three methods were
 17 also calculated.

18 The border of the lake for all the models was an isobath at 0.4 metres, obtained by
 19 interpolating bathymetrically measured depth data and terrain elevation data obtained by aero-
 20 photogrammetry. The isobath was converted into a polygon, which was used to determine a
 21 raster model within the borders of the polygon. Table 5 also shows that the surface, perimeter
 22 and volume of the lake, regardless of the formula used, greatly depend on the model
 23 developed by interpolation.

Table 6. Perimeter and surface area of Lake Vrana at various water levels, for the most suitable (OCK) interpolation method

Comment [a19]: Changed name of table

Water level (in reference to the Prosika gauge)		Perimeter (km)	Surface area (km ²)
Maximum*	2.36	38.541	33.064
Mean	0.93	38.338	30.815
Minimum	0.15	34.974	29.177

*Within Lake Vrana Nature Park

The surface area of Lake Vrana, in relation to its water level (which annually oscillates by 1.93 m) varies by almost 4 km² (Table 6). It can be obtained by manual vectorisation based on a geo-referential digital orthophoto (29.412 km²). The process is relatively simple, and the contour of the lake is represented by the border between the water and land, defined by subjective visual approximation. However, 4.6% of the lake's surface area is covered in dense vegetation (*Phragmitetalia*), which makes determining the surface area a more complex task. Considering the limitations of the aforementioned method, the research employed previously stated methods for determining the lake's surface area.

The total surface area of the lake is 30.815 km², calculated based on the 0.93 m isobath (mean water level in the observed period from 1947 to 2007) obtained by interpolating data on an elevation of the surrounding terrain and depth of the lake. The interpolation method provided good results, because most of the lake's shore is flattened featuring mild slopes and almost no anomalies in data values obtained by bathymetric survey and aero-photogrammetry. The method was also tested by field work, using a precise GPS. The device was used to record information on the most distant borders of the lake at six randomly chosen locations. Since the interpolated border of the lake was transferred into GPS, it was easy to determine the deviation.

The average width of the lake is 2201.4 metres (minimum 262.26 and maximum 3469.31 metres). The average length of the longitudinal profiles is 8765.43 metres (minimum 1843.55 and maximum 13 245.34 m). These values were obtained by analyzing 68 transverse (northeast-southwest) and 17 longitudinal (southeast-northwest) profiles at 200-metre intervals (at the water level of 0.42 metres).

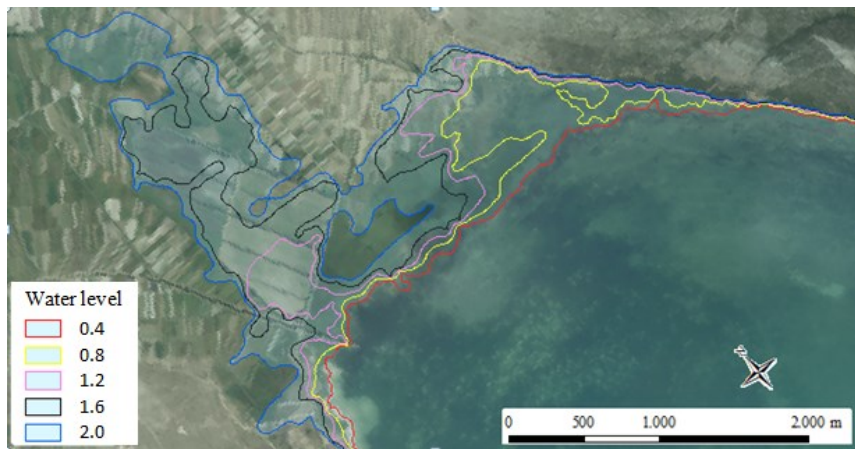

4 Discussion and Conclusion

Since the surface area and water level of Lake Vrana change throughout the year, this research visualized the annual water level oscillation (a scenario was made for the northwestern Jasen inundation area, outside the Nature Park), in case the Jasen water pump stopped working (Fig. 11). A section of the flooded habitats and cadastre plots within the Nature Park were also determined (Table 7), at the water level of 2 metres (Fig. 12).

Table 7. Percentage of flooded habitats at the water level of 2 m in reference to the Prosika gauge

NKS_DESCRIPTION	Flooded area (ha)	Total area of the habitat in the NP (ha)	Percentage (%)
Complex mosaic of crops	37.8	206.3	18.3
Illyrian-Sub-Mediterranean river valley meadows / Mediterranean halophytic <i>Juncus</i> species	32.6	34.9	93.4
Mixed evergreen forests and holm oak maquis	15.6	696.3	2.2
Brambles	6.6	685.9	1.0
Shore uncovered or rarely covered by vegetation	4.4	6.3	70.9
Illyrian-Sub-Mediterranean river valley meadows	2.6	2.6	100.0
Tree lines at the edges of cultivated areas	2.1	7.2	29.5
Brambles / Thermophile flooded underbrush	1.2	3.5	34.9
Thermophile flooded underbrush	0.6	1.2	50.0
Aleppo pine plantations	0.6	65.6	0.9
Tyrrhenian-Adriatic limestone	0.6	1.0	60.3
Consolidated arable land with monoculture crops (cereals)	0.6	1.1	52.7
Man-made or industrial habitats	0.5	11.2	4.6

The water level map at 2 m was overlaid with the map of habitats for Lake Vrana Nature Park to the scale of 1:5000. The map was made in accordance with the rules of National Croatian Habitat Classification and comprises 30 classes of habitats (Jelaska, 2010). A sudden change in the water level can change the ecological features of a particular habitat, affecting the flora and fauna of Lake Vrana Nature Park. The analysis concluded that almost half the habitats are endangered if the water level rises to 2 metres. The highest level of threat (100%) relates to Illyrian-Sub-Mediterranean river valley meadows. and the lowest level (1%) relates to brambles. It is worth noting that 52.7% of the endangered areas are consolidated arable lands with monoculture crops (cereals), while 18.3% (37.8 ha) are complex mosaics of crops.

Figure 11. Annual water level oscillation in the northern part of Lake Vrana Nature Park (probable scenario in case the Jasen water pump stops working)

Most are used for intensive agricultural purposes. The northern part of the Park features horticultural plants with multiannual crop rotations. Plants include mostly hybrid species. Various agro-technical methods are used in order to produce a better level of crop success, as well as fertilizers and chemical components for plant protection (JUPPVJ, 2010). In the northwestern lake area, there is a mixed culture of olive fields, vineyards, horticulture and some cereal crops (JUPPVJ, 2010). Should the water level rise by 2 metres, it would partially or completely threaten 45.94% of the cadastre plots. In the northern part of the Park (a flatter area), flooding would threaten the entire area. In the northwestern part, flooding would mostly threaten areas at a lower elevation. These areas have been more susceptible to flooding in the past, as is evident from the specific shape of the field parcels (especially in the northwestern part). The parcels there are narrow (10 metres on average) and extremely elongated (150 metres). The inclination of these parcels (2-5°) is perpendicular to the lake.

8

9 The results of this research show that the output results of the digital terrain modelling and
10 corresponding analyses depend on the data gathering methods, density of samples,
11 interpolation methods, terrain features (mostly vertical dissection), pixel size and algorithms
12 applied. In the research, 14 methods of interpolation were compared; 6 deterministic and 8
13 geostatistical. Of the five most common methods for gathering elevation data and comparing
14 interpolation methods, two sets of data were used (depth and elevation). They were obtained
15 by various methods, techniques and procedures: bathymetry and aero-photogrammetry. The
16 conclusion is that there is no universal method of interpolation which shows the best results in
17 both sets of data, since the output results depend on the data gathering method. For example,

1 an optimal method for developing a DEM of the lake's shore was developed, but it turned out
2 to be inadequate for developing a DEM of the lake's bottom. In addition, regardless of the
3 fact that certain authors point out either deterministic or geostatistical methods as more
4 advantageous, it is important to note that there is no single best interpolation method, since
5 they are all conditioned by spatial and temporal components. This means that the result of the
6 comparison and selection of the best method are in fact provisional and dependent on time
7 and space components, the technology used to gather and process data, and the area of
8 research.

9 The fact that geostatistical methods of interpolation employ mathematical functions and the
10 probability theory was one of the reasons for hypothesizing that geostatistical methods would
11 be better interpolators. This was proven, but the research also showed that the differences
12 between geostatistical and deterministic methods were negligible. The multi-quadratic
13 function, as the globally most commonly accepted method, was proven to be the best radial
14 basic function, but also one of the best deterministic interpolation methods in general.

15 In order to develop a digital model from the bathymetrically gathered data, 14 interpolation
16 methods were compared in two phases. In the first phase (which used 12 851 bathymetrically
17 measured points), all the methods compared showed good results, due to the low vertical
18 dissection of the terrain. By using the method of cross-validation and analyzing statistical
19 parameters, the conclusion was that the best results were yielded by the simple cokriging
20 method (the standard deviation was 0.197 m) Fig. 13. The range of the standard deviation for
21 all 14 methods was between 0.197 and 0.249 m. Due to characteristic issues with output
22 results and the problem of extrapolating data in the first phase, the process of comparing
23 interpolation methods was repeated for the sample of 30 233 points within Lake Vrana Nature
24 Park. The output results in the second phase were notably different, and the majority of
25 methods applied showed imperfections. According to all the statistical parameters, the best
26 method of interpolation was ordinary cokriging. Along with ordinary cokriging, good results
27 were shown by the inverse distance weighting method, RBF – multiquadratic method and
28 ordinary kriging. The standard deviation for all three methods was less than 0.5 m. These
29 methods were compared by graphic representation, calculation and comparison of the
30 profiles, surface area and volume of the lake. The conclusion was that there were no
31 significant differences between the statistical indicators in deterministic or geostatistical
32 methods, whether the parameters were determined automatically or manually. However, by

1 testing the ordinary kriging method, the conclusion was that the reduction in the distance
2 positively affected standard deviation, but negatively affected approximation in the areas that
3 were not included in the direct survey. The interpolated values in those areas turned out to be
4 much greater than the values actually measured at the surrounding points.

5 Based on the optimal method of interpolation, the lake's surface area, perimeter and volume
6 were calculated at the water level of 0.4 meters in reference to the Prosika gauge. The surface
7 area of the lake is 29.865 km², the perimeter is 35.851 km and the volume is 50 076 679 m³.
8 During the bathymetric survey, the conclusion was that a low frequency (30 kHz) could not
9 penetrate the very thick, intertwined "sediment" vegetation which formed the new bottom of
10 the lake. Another problem with low frequency is occasionally significant leaps in profiles,
11 especially in places where the frequency managed to penetrate the vegetation or mud. In order
12 to perform a detailed analysis, a sediment profiler with a frequency of up to 15 kHz should be
13 used to gain detailed information about the layers on the lake's bottom (Lafferty et al. ,2005;
14 Pribičević et al., 2007).

15 All the analyses and conclusions derived can be used for further research on data gathering
16 methods, interpolation methods, methods of spatial resolution selection and methods of digital
17 terrain analysis. In any future research of Lake Vrana, it would be useful to extend the profiles
18 during the survey, if a single beam sounder is used, so that the distance between the profiles is
19 no greater than 50 metres. In that case the relation between the profiles and the data gathered
20 from the profiles (every 10 metres) would be much more proportional. In addition, it would
21 be useful to compare the results of the development of the lake's bottom model using single
22 beam, multi-beam and laser sounder techniques. It is important to note that the more efficient
23 techniques, such as multi-beam ultrasound or laser measurement, might not yield significantly
24 better results due to the morphology of the bottom and the relatively high percentage of dense,
25 native vegetation. The portion of the bottom surveyed would increase in relation to the
26 portion surveyed with the single beam sounder, but the costs of such research would
27 drastically increase, as well as the amount of data yielded for the processing. In that case,
28 processing stations would have to be employed as well. A frequency of under 15 kHz is
29 recommended for future research, in order to determine the density and volume of sediments.
30 Since 4.6% of the lake's surface is covered in dense vegetation, it was difficult to determine
31 the exact borders. The dense vegetation prevents sounders from effectively reaching the
32 surface. In order to avoid extrapolation in the bordering areas, the research employed
33 elevation data obtained by aero-photogrammetry and stereo-restitution, where the average

1 distance between the elevation points was 90 metres. If future interpolation projects aim at
2 higher level of precision in the bordering areas, it will be necessary to reduce the distance
3 between the elevation points. Recommended methods include aerolaser or aero-
4 photogrammetry. In this case, the distance between the points should be less during stereo-
5 restitution (maximum 10 metres).

6 The data measured and evaluated enable the development of hydrological and hydro-technical
7 studies which would result in an optimal water level, ensure a biological minimum and
8 economical water minimum, and optimize the water system. In order to determine the volume
9 of the lake, it was necessary to map the lake's bottom, gather data required for the
10 development of the digital elevation model, and make a topographic map of the lake's bottom
11 and shoreline relative to its optimal water level, thus creating a sound basis for future
12 activities.
