Table 3 (table 2 in manuscript): Details of key parameters and data sources used in model calibration (to 1 d.p)

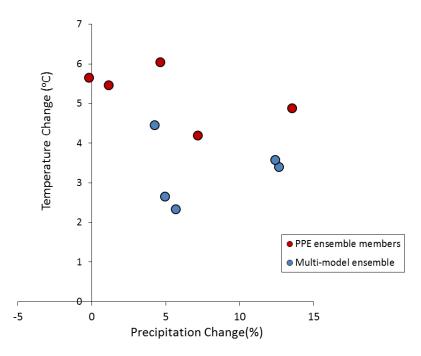

Figure 1: Scatterplot showing projected average annual change in temperature (°C) and precipitation (%) between 1968-1997 and 2060-2089. Global climate models included in the multi-model ensemble are NCARP, ECHO, ECHAM5, CSIRO, CGCM3 and CSRIOs of the A1b scenario).

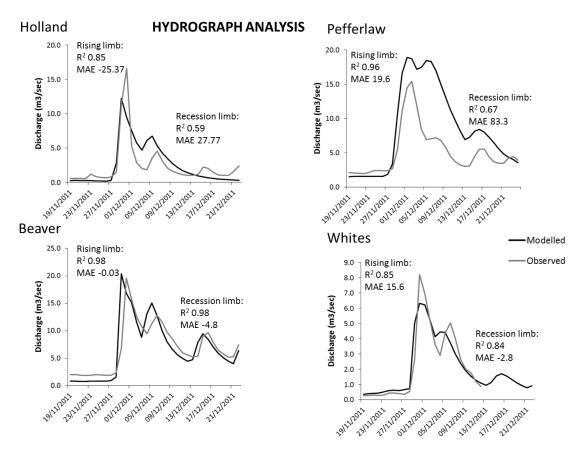

Figure 2: Analysis of INCA model fit to event data at tributary outflow. Rising and recession limb at analysed separately for R2 and MAE to ascertain model representation of catchment responses to precipitation events. All events analysed during four day period of intense precipitation in November 2011. Although these event curves can be used to confirm model representation of reality, it should be noted they should not be used to compare event response times between catchments.

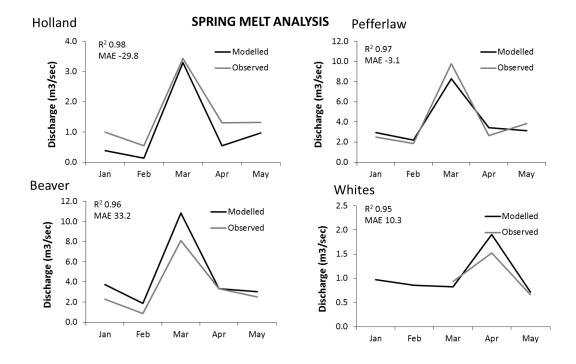

Figure 3: Analysis of model response to observed spring melt. All results presented represent the spring melt of 2010, except in the case of the Whites River, where observations are rarely collected during winter, and an average of 2010 and 2011 results were required to provide sufficient data for analysis.

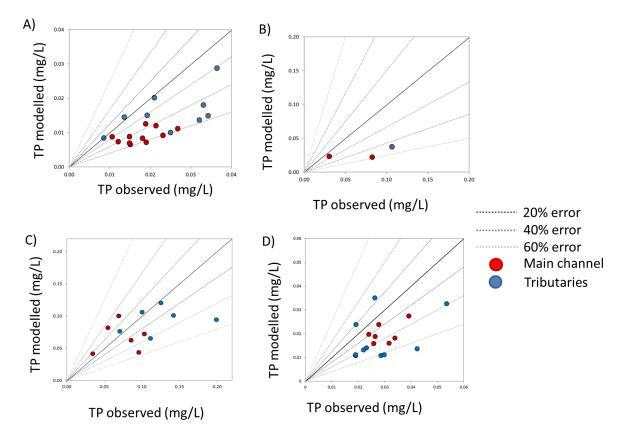

Figure 4: Spatial variability in model accuracy of TP concentrations throughout INCA models calibrated across multiple reaches, illustrating relative model error in A) Holland, B) Pefferlaw, C) Beaver and D) Whites catchments. Data represents average TP concentrations over calibrated period.

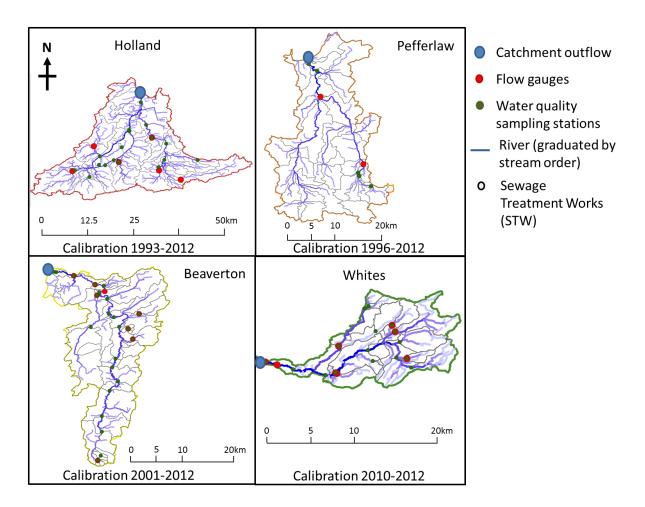

Figure 5: Detailed site schematic of each study area, including location of sewage treatment work (STW) inputs
