Abstract

The two-dimensional advection-dispersion equations coupled with sequential first-order decay reactions involving arbitrary number of species in groundwater system is considered to predict the two-dimensional plume behavior of decaying contaminant such as radionuclide and dissolved chlorinated solvent. Generalized analytical solutions in compact format are derived through the sequential application of the Laplace, finite Fourier cosine, and generalized integral transform to reduce the coupled partial differential equation system to a set of linear algebraic equations. The system of algebraic equations is next solved for each species in the transformed domain, and the solutions in the original domain are then obtained through consecutive integral transform inversions. Explicit form solutions for a special case are derived using the generalized analytical solutions and are compared with the numerical solutions. The analytical results indicate that the analytical solutions are robust, accurate and useful for simulation or screening tools to assess plume behaviors of decaying contaminants.

Keywords: Parsimonious analytical model; reactive transport; first-order decay reaction; Bateman-type source; radionuclide; dissolved chlorinated solvent.

1. Introduction

Experimental and theoretical studies have been undertaken to understand the fate and transport of dissolved hazardous substances in subsurface environments because that human health is threatened by a wide spectrum of contaminants in groundwater and soil. Analytical models are essential and efficient tools for understanding pollutants behavior in subsurface environments. Several analytical solutions for single-species transport problems have been reported for simulating the transport of various contaminants (Batu, 1989; 1993; 1996; Chen et al., 2008a; 2008b; 2011; Gao et al., 2010; 2012; 2013; Leij et al., 1991; 1993; Park and Zhan, 2001; Pérez Guerrero and Skaggs, 2010 ; Pérez Guerrero et al., 2013 ; van Genuchten and Alves, 1982; Yeh, 1981; Zhan et al., 2009; Ziskind et al., 2011). Transport processes of some contaminants such as radionuclides, dissolved chlorinated solvents and nitrogen generally involve a series of first-order or pseudo first-order sequential decay chain reactions. During migrations of decaying contaminants, mobile and toxic successor products may sequentially form and move downstream with elevated concentrations. Single-species analytical models do not permit transport behaviors of successor species of these decaying contaminants to be evaluated. Analytical models for multispecies transport equations coupled with first-order sequential decay reactions are useful tools for synchronous determination of the fate and transport of the predecessor and successor species of decaying contaminants. However, there are few analytical solutions for coupled multispecies transport equations compared to a large body of analytical solutions in the literature pertaining to the single-species advective-dispersive transport subject to a wide spectrum of initial and boundary conditions.

Mathematical approaches have been proposed in the literature to derive a limited number of one-dimensional analytical solutions or semi-analytical solutions for multispecies advective–dispersive transport equations sequentially coupled with first-order decay reactions. These include direct integral transforms with sequential substitutions (Cho, 1971; Lunn et al., 1996; van Genuchten, 1985, Mieles

and Zhan, 2012), decomposition by change-of-variables with the help of existing single-species analytical solutions (Sun and Clement, 1999; Sun et al., 1999a; 1999b), Laplace transform combined with decomposition of matrix diagonization (Quezada et al., 2004; Srinivasan and Clememt, 2008a; 2008b), decomposition by change-of-variables coupled with generalized integral transform (Pérez Guerrero et al., 2009; 2010), sequential integral transforms in association with algebraic decomposition (Chen et al., 2012a; 2012b).

Multi-dimensional solutions are needed for real world applications, making them more attractive than one-dimensional solutions. Bauer et al. (2001) presented the first set of semi-analytical solutions for one-, two-, and three-dimensional coupled multispecies transport problem with distinct retardation coefficients. Explicit analytical solutions were derived by Montas (2003) for multi-dimensional advective-dispersive transport coupled with first-order reactions for a three-species transport system with distinct retardation coefficients of species. Quezada et al. (2004) extended the Clement (2001) strategy to obtain Laplace-domain solutions for an arbitrary decay chain length. Most recently, Sudicky et al. (2013) presented a set of semi-analytical solutions to simulate the three-dimensional multi-species transport subject to first-order chain-decay reactions involving up to seven species and four decay levels. Basically, their solutions were obtained species by species using recursion relations between target species and its predecessor species. For a straight decay chain, they derived solutions for up to four species and no generalized expressions with compact formats for any target species were obtained. Note that their solutions were derived for the first-type (Dirichlet) inlet conditions which generally bring about physically improper mass conservation and significant errors in predicting the concentration distributions especially for a transport system with a large longitudinal dispersion coefficient (Barry and Sposito, 1988; Parlange et al., 1992). Moreover, in addition to some special cases, the numerical Laplace transforms are required to obtain the original time domain solution. Besides the straight decay chain, the analytical model by Clement (2001) and Sudicky (2013) can

account for more complicated decay chain problems such as diverging, converging and branched decay chains.

Based on the aforementioned reviews, this study presents a parsimonious explicit analytical model for two-dimensional multispecies transport coupled by a series of first-order decay reactions involving an arbitrary number of species in groundwater system. The derived analytical solutions have four salient features. First, the third-type (Robin) inlet boundary conditions which satisfy mass conservation are considered. Second, the solution is explicit, thus solution can be easily evaluated without invoking the numerical Laplace inversion. Third, the generalized solutions with parsimonious mathematical structures are obtained and valid for any species of a decay chain. The parsimonious mathematical structures of the generalized solutions are easy to code into a computer program for implementing the solution computations for arbitrary target species. Fourth, the derived solutions can account for any decay chain length. The explicit analytical solutions have applications for evaluation of concentration distribution of arbitrary target species of the real-world decaying contaminants. The developed parsimonious model is robustly verified with three example problems and applied to simulate the multispecies plume migration of dissolved radionuclides and chlorinated solvent.

2. Governing equations and analytical solutions

2.1 Derivation of analytical solutions

This study consider the problem of decaying contaminant plume migration. The source zone is located in the upstream of groundwater flow. The source zone can represent leaching of radionuclide from a radioactive waste disposal facility or release of chlorinated solvent from the residual NAPL phase into the aqueous phase. After these decaying contaminants enter the aqueous phase, they migrate by one-dimensional advection with flowing groundwater and by simultaneously longitudinal and transverse dispersion processes. While migrating in the groundwater system, the contaminants undergo

linear isothermal equilibrium sorption and a series of sequential first-order decaying reactions. Sudicky et al. (2013) provided the detailed modeling scenario. The scenario considered in this study can be ideally described as shown in Fig. 1. A steady and uniform velocity in the x direction is considered in Fig. 1. The governing equations describing two-dimensional reactive transport of the decaying contaminants and their successor species undergoing linear isothermal equilibrium sorption and a series of sequential first-order decaying reactions can be mathematically written as

$$D_L \frac{\partial^2 C_1(x,y,t)}{\partial x^2} - v\frac{\partial C_1(x,y,t)}{\partial x} + D_T \frac{\partial^2 C_1(x,y,t)}{\partial y^2} - k_1 R_1 C_1(x,y,t) = R_1 \frac{\partial C_1(x,y,t)}{\partial t} \quad (1a)$$

$$D_L \frac{\partial^2 C_i(x,y,t)}{\partial x^2} - v\frac{\partial C_i(x,y,t)}{\partial x} + D_T \frac{\partial^2 C_i(x,y,t)}{\partial y^2} - k_i R_i C_i(x,y,t) + k_{i-1} R_{i-1} C_{i-1}(x,y,t) = R_i \frac{\partial C_i(x,y,t)}{\partial t} \quad i = 2...N. \quad (1b)$$

where $C_i(x,y,t)$ is the aqueous concentration of species i [$\mathbf{ML^{-3}}$]; x and y are the spatial coordinates in the groundwater flow and perpendicular directions [**L**], respectively; t is time [**T**]; D_L and D_T represent the longitudinal and transverse dispersion coefficients [$\mathbf{L^2T^{-1}}$], respectively; v is the average steady and uniform pore-water velocity [$\mathbf{LT^{-1}}$]; k_i is the first-order decay rate constant of species i [$\mathbf{T^{-1}}$]; R_i is the retardation coefficient of species i [-]. Note that these equations consider that the decay reactions occur simultaneously in both the aqueous and sorbed phases. If the decay reactions occur only in the aqueous phase, the retardation coefficients in the decay terms in the right-hand sides of Eqs. (1a) and (1b) become unity. For such case, k_i and k_{i-1} in the left-hand sides could be modified as $\frac{k_i}{R_i}$ and $\frac{k_{i-1}}{R_{i-1}}$ to facilitate the application of the derived analytical solutions obtained by Eqs. (1a) and (1b).

The initial and boundary conditions for solving Eqs. (1a) and (1b) are:

$$C_i(x,y,t=0)=0 \quad 0\le x\le L, 0\le y\le W \qquad i=1...N. \tag{2}$$

$$-D_L\frac{\partial C_i(x=0,y,t)}{\partial x}+vC_i(x=0,y,t)=vf_i(t)\left[H(y-y_1)-H(y-y_2)\right] \qquad t\ge 0 \qquad i=1...N. \tag{3}$$

$$\frac{\partial C_i(x=L,y,t)}{\partial x}=0 \qquad t\ge 0, 0\le y\le W \qquad i=1...N. \tag{4}$$

$$\frac{\partial C_i(x,y=0,t)}{\partial y}=0 \qquad t\ge 0, 0\le x\le L \qquad i=1...N. \tag{5}$$

$$\frac{\partial C_i(x,y=W,t)}{\partial y}=0 \qquad t\ge 0, 0\le x\le L \qquad i=1...N. \tag{6}$$

where $f_i(t)$ is the arbitrary time-dependent source concentration of species *i* applied at the source segment ($H(y-y_1)-H(y-y_2)$) at boundary (x = 0) which will be specified later [L], $H(\bullet)$ is the Heaviside function, L and W are the length and width of the transport system under consideration [L]. Eq. (2) implies that the transport system is free of solute mass at the initial time.

Eq. (3) means that a third-type boundary condition satisfying mass conservation at the inlet boundary is considered. Eq. (4) considers the concentration gradient to be zero at the exit boundary based on the mass conservation principle. Such a boundary condition has been widely used for simulating solute transport in a finite-length system. Eqs. (5) and (6) assume no solute flux across the lower and upper boundaries. It is noted that in Eq. (3), we assume arbitrary time-dependent sources of species *i* uniformly distributed at the segment ($y_1\le y\le y_2$) of the inlet boundary ($x=0$), the so-called Heaviside function source concentration profile. Relative to the first type boundary conditions used by Sudicky et al. (2013), the third-type boundary conditions which satisfy mass conservation at the inlet boundary (Barry and Sposito, 1988; Parlange et al., 1992) are used herein. Sudicky et al. (2013) considered the source concentration profiles as Gaussian or Heaviside step functions. If Gaussain distributions are desired, we can easily replace the Heaviside function in the right-hand side of Eq.

(3) with a Gaussian distribution.

Eqs. (1)-(6) can be expressed in dimensionless form as

$$\frac{1}{Pe_L}\frac{\partial^2 C_1(X,Y,Z)}{\partial X^2}-\frac{\partial C_1(X,Y,Z)}{\partial X}+\frac{\rho^2}{Pe_T}\frac{\partial^2 C_1(X,Y,Z)}{\partial Y^2}-\kappa C_1(X,Y,Z)=R_1\frac{\partial C_1(X,Y,T)}{\partial T} \tag{7a}$$

$$\frac{1}{Pe_L}\frac{\partial^2 C_i(X,Y,T)}{\partial X^2}-\frac{\partial C_i(X,Y,T)}{\partial X}+\frac{\rho^2}{Pe_T}\frac{\partial^2 C_i(X,Y,T)}{\partial Y^2} \quad i=2...N. \tag{7b}$$
$$-\kappa_i C_i(X,Y,T)+\kappa_{i-1}C_{i-1}(X,Y,T)=R_i\frac{\partial C_i(X,Y,T)}{\partial T}$$

$$C_i(X,Y,T=0)=0 \quad 0\le X\le 1, 0\le Y\le 1 \quad i=1...N. \tag{8}$$

$$-\frac{1}{Pe_L}\frac{\partial C_i(X=0,Y,T)}{\partial X}+C_i(X=0,Y,Z)=f_i(T)\left[H(Y-Y_1)-H(Y-Y_2)\right] \; T\ge 0, i=1...N. \tag{9}$$

$$\frac{\partial C_i(X=1,Y,T)}{\partial X}=0 \quad T\ge 0, 0\le Y\le 1 \quad i=1...N. \tag{10}$$

$$\frac{\partial C_i(X,Y=0,T)}{\partial Y}=0 \quad T\ge 0, 0\le X\le 1 \quad i=1...N. \tag{11}$$

$$\frac{\partial C_i(X,Y=1,T)}{\partial Y}=0 \quad T\ge 0, 0\le X\le 1 \quad i=1...N. \tag{12}$$

where $X=\frac{x}{L}$, $Y=\frac{y}{W}$, $Y_1=\frac{y_1}{W}$, $Y_2=\frac{y_2}{W}$, $T=\frac{vt}{L}$, $Pe_L=\frac{vL}{D_L}$, $Pe_T=\frac{vL}{D_T}$, $\rho=\frac{L}{W}$.

Our solution strategy used is extended from the approach proposed by Chen at al. (2012a; 2012b). The core of this approach is that the coupled partial differential equations are converted into an algebraic equation system via a series of integral transforms and the solutions in the transformed domain for each species are directly and algebraically obtained by sequential substitutions.

Following Chen et al. (2012a; 2012b), the generalized analytical solutions in compact formats can be obtained as follows (with detailed derivation provided in Appendix A)

$$C_i(X,Y,T)$$

$$= f_i(T)\Phi(n=0) + e^{\frac{Pe_L}{2}X}\sum_{l=1}^{\infty}\frac{K(\xi_l,X)}{N(\xi_l)}\left[p_i(\xi_l,n,T)+q_i(\xi_l,n,T)\right]\Phi(n=0)\Theta(\xi_l) \quad (13)$$

$$+2\sum_{n=1}^{n=\infty}\left\{f_i(T)\Phi(n)+e^{\frac{Pe_L}{2}X}\sum_{l=1}^{\infty}\frac{K(\xi_l,X)}{N(\xi_l)}\left[p_i(\xi_l,n,T)+q_i(\xi_l,n,T)\right]\Phi(n)\Theta(\xi_l)\right\}\cos(n\pi Y)$$

where $\Phi(n)=\begin{cases}Y_2-Y_1 & n=0\\ \dfrac{\sin(n\pi Y_2)-\sin(n\pi Y_1)}{n\pi} & n=1,2,3...\end{cases}$, ξ_l is the eigenvalue, determined from the equation $\xi_l\cot\xi_l-\dfrac{{\xi_l}^2}{Pe_L}+\dfrac{Pe_L}{4}=0$, $\Theta(\xi_l)=\dfrac{Pe_L\xi_l}{\frac{{Pe_L}^2}{4}+{\xi_l}^2}$, $K(\xi_l,X)=\dfrac{Pe_L}{2}\sin(\xi_l X)+\xi_l\cos(\xi_l X)$,

$$N(\xi_l)=\frac{2}{\frac{{Pe_L}^2}{4}+Pe_L+{\xi_l}^2},$$

$$p_i(\xi_l,n,T)=f_i(T)-\beta_i e^{-\alpha_i T}\int_0^T f_i(\tau)e^{\alpha_i\tau}d\tau \quad (14)$$

and

$$q_i(\xi_l,n,T)=\sum_{k=0}^{k=i-2}\left(\beta_{i-k-1}\prod_{j_1=0}^{j_1=k}\sigma_{i-j_1}\right)\sum_{j_2=0}^{j_2=k+1}\frac{e^{-\alpha_{i-j_2}T}\int_0^T e^{\alpha_{i-j_2}\tau}f_{i-k-1}(\tau)d\tau}{\prod_{j_3=i-k-1,\,j_3\neq i-j_2}^{j_3=i}\left(\alpha_{j_3}-\alpha_{i-j_2}\right)} \quad (15)$$

where $\alpha_i(\xi_l)=\dfrac{\kappa_i}{R_i}+\dfrac{\rho^2n^2\pi^2}{Pe_T R_i}+\dfrac{Pe_L}{4R_i}+\dfrac{{\xi_l}^2}{Pe_L R_i}$, $\beta_i(\xi_l)=\dfrac{Pe_L}{4R_i}+\dfrac{{\xi_l}^2}{Pe_L R_i}$, $\sigma_i=\dfrac{\kappa_{i-1}}{R_i}$

Concise expressions for arbitrary target species such as described in Eqs. (13) to (15) facilitate the development of a computer code for implementing the computations of the analytical solutions.

The generalized solutions of Eq. (13) accompanied by two corresponding auxiliary functions $p_i(\xi_l,n,T)$ and $q_i(\xi_l,n,T)$ in Eqs. (14)-(15) can be applied to derive analytical solutions for some

special-case inlet boundary sources. Here the time-dependent decaying source which represents the specific release mechanism defined by the Bateman equations (van Genuchten, 1985) is considered. A Bateman-type source is described by

$$f_i(t) = \sum_{m=1}^{i} b_{im} e^{-\delta_m t} \tag{16a}$$

or in dimensionless form,

$$f_i(T) = \sum_{m=1}^{m=i} b_{in} e^{-\lambda_m T} \tag{16b}$$

The coefficients b_{im} and $\delta_m = \mu_m + \gamma_m$ account for the first-order decay reaction rate (μ_m) of each species in the waste source and the release rate (γ_m) of each species from the waste source, $\lambda_m = \frac{\delta_m L}{v}$.

By substituting Eq. (16b) into Eqs. (13)-(15), we obtain

$$\begin{aligned} & C_i(X,Y,T) \\ & = \sum_{m=1}^{m=i} b_{im} e^{-\lambda_m T} \Phi(n=0) + e^{\frac{Pe_L}{2}X} \sum_{l=1}^{\infty} \frac{K(\xi_l, X)}{N(\xi_l)} \left[p_i(\xi_l, n, T) + q_i(\xi_l, n, T) \right] \Phi(n=0) \Theta(\xi_l) \\ & + 2 \sum_{n=1}^{n=\infty} \left\{ \sum_{m=1}^{m=i} b_{im} e^{-\lambda_m T} \Phi(n) + e^{\frac{Pe_L}{2}X} \sum_{l=1}^{\infty} \frac{K(\xi_l, X)}{N(\xi_l)} \left[p_i(\xi_l, n, T) + q_i(\xi_l, n, T) \right] \Phi(n) \Theta(\xi_l) \right\} \cos(n\pi Y) \end{aligned} \tag{17}$$

where

$$p_i(\xi_l, n, T) = \sum_{m=1}^{m=i} b_{i,m} \cdot e^{-\lambda_m T} - \beta_i \sum_{m=1}^{m=i} b_{i,m} \frac{e^{-\lambda_m T} - e^{-\alpha_i T}}{\alpha_i - \lambda_m} \tag{18}$$

and

194 $$p_i(\xi_l,n,T)=\sum_{k=0}^{k=i-2}\left(\beta_{i-k-1}\prod_{j_1=0}^{j_1=k}\sigma_{i-j_1}\right)\sum_{j_2=0}^{j_2=k+1}\frac{\sum_{m=1}^{m=i-k-1}\frac{b_{i-k-1,m}\left(e^{-\lambda_m T}-e^{-\alpha_{i-j_2}T}\right)}{\alpha_{i-j_2}-\lambda_m}}{\prod_{j_3=i-k-1,\,j_3\neq i-j_1}^{j_3=i}\left(\alpha_{j_3}-\alpha_{i-j_2}\right)} \quad (19)$$

195

196 ***2.2 Convergence behavior of the Bateman-type source solution***

197 Based on the special-case analytical solutions in Eq. (17) supported by two auxiliary functions,
198 defined in Eqs. (18) and (19), a computer code was developed in FORTRAN 90 language with double
199 precision. The details of the FORTRAN computer code are described in Supplement. The derived
200 analytical solutions in Eqs. (17)-(19) consist of summations of double infinite series expansions for
201 the finite Fourier cosine and generalized integral transform inversions, respectively. It is
202 straightforward to sum up these two infinite series expansions term by term. To avoid time-consuming
203 summations of these infinite series expansions, the convergence tests should be routinely executed to
204 determine the optimal number of the required terms for evaluating analytical solutions to the desired
205 accuracies. Two-dimensional four-member radionuclide decay chain
206 $^{238}Pu \rightarrow ^{234}U \rightarrow ^{230}Th \rightarrow ^{226}Ra$ is considered herein as convergence test example 1 to demonstrate
207 the convergence behavior of the series expansions. This convergence test example 1 is modified from
208 a one-dimensional radionuclide decay chain problem originated by Higashi and Pigford (1980) and
209 later applied by van Genuchten (1985) to illustrate the applicability of their derived solution. The
210 important model parameters related to this test example are listed in Tables 1 and 2. The inlet source
211 is chosen to be symmetrical with respect to the x-axis and conveniently arranged in the
212 $40\,m \le y \le 60\,m$ segment at the inlet boundary.

213 In order to determine the optimal term number of series expansions for the finite Fourier cosine
214 transform inverse to achieve accurate numerical evaluation, we specify a sufficiently large number of

215 series expansions for the generalized transform inverse so that the influence of the number of series
216 expansions for the generalized integral transform inverse on convergence of series expansion for finite
217 Fourier cosine transform inverse can be excluded. A similar concept is used when investigating the
218 required number of terms in the series expansions for the generalized integral transform inverse. An
219 alternative approach is conducted by simultaneously varying the term numbers of series expansions
220 for the generalized integral transform inverse and the finite Fourier cosine transform inverse.

221 Tables 3, 4 and 5 give results of the convergence tests up to 3 decimal digits of the solution
222 computations along the three transects (inlet boundary at x =0 m, x =25 m, and exit boundary at x
223 =250m). In these tables M and N are defined as the numbers of terms summed for the generalized
224 integral transform inverse and finite Fourier cosine transform inverse, respectively. It is observed that
225 M and N are related closely to the true values of the solutions. For smaller true values, the solutions
226 must be computed with greater M and N . However, convergences can be drastically speeded up if
227 lower calculation precision (e.g. 2 decimal digits accuracy) is acceptable. For example,
228 $(M, N) = (100,200)$ is sufficient for 2 decimal digits accuracy, while for 3 decimal digits accuracy we
229 need $(M, N) = (1600,8000)$. Two decimal digits accuracy is acceptable for most practical problems.
230 It is also found that M increases and N decreases with increasing x.

231 To further examine the series convergence behavior, example 2 considers a transport system of
232 large aspect ratio ($\frac{L}{W} = \frac{2{,}500m}{100m}$) and a narrower source segment, $45\,m \le y \le 55\,\mathrm{m}$, on the inlet
233 boundary. Tables 6 and 7 present results of the convergence tests of the solution computations along
234 two transects (inlet boundary and x =250 m). Tables 6 and 7 also show similar results for the
235 dependences of M and N on x. Note that larger M and N are required for each species in this
236 test example, suggesting that the evaluation of the solution for a large aspect ratio requires more series
237 expansion terms to achieve the same accuracy as compared to example 1. Detailed results of the

convergence test examples 1 and 2 are provided in Supplement.

Using the required numbers determined from the convergence test, the computational time for evaluation of the solutions at 50 different observations only takes 3.782s, 11.325s, 23.95s and 67.23s computer clock time on an Intel Core i7-2600 3.40 MHz PC for species 1, 2, 3, and 4 in the comparison of example 1.

3. Results and discussion

3.1 Comparison of the analytical solutions with the numerical solutions

Three comparison examples are considered to examine the correctness and robustness of the analytical solutions and the accuracy of the computer code. The first comparison example is the four-member radionuclide transport problem used in the convergence test example 1. The second comparison example considers the four-member radionuclide transport problem used in the convergence test example 2. The third comparison example is used to test the accuracy of the computer code for simulating the reactive contaminant transport of a long decay chain. The three comparison examples are executed by comparing the simulated results of the derived analytical solutions with the numerical solutions obtained using the Laplace transformed finite difference (LTFD) technique first developed by Moridis and Reddell (1991). A computer code for the LTFD solution are written in FORTTRAN language with double precision. The details of the FORTRAN computer code is described in Supplement.

Figures 2, 3 and 4 depicts the spatial concentration distribution along one longitudinal direction ($y = 50$ m) and two transverse directions ($x = 0$ m and $x = 25$ m) for convergence test example 1 at t = 1,000 year obtained from analytical solutions and numerical solutions. Figures 5, 6 and 7 present the spatial concentration distribution along one longitudinal direction ($y = 50$ m) and two transverse directions ($x = 0$ m and $x = 25$ m) for the convergence test example 2 at t = 1,000 year obtained

from analytical solutions and numerical solutions. Excellent agreements between the two solutions for both examples are observed for a wide spectrum of concentration, thus warranting the accuracy and robustness of the developed analytical model.

The third example involves a 10 species decay chain previously presented by Srinivasan and Clement (2008a) to evaluate the performance of their one-dimensional analytical solutions. The relevant model parameters are summarized in Tables 8 and 9. Our computer code is also compared against the LTFD solutions for this example. Figure 8 depicts the spatial concentration distribution at t = 20 days obtained analytically and numerically. Again there is excellent agreement between the analytical and numerical solutions, demonstrating the performance of our computer code for simulating transport problems with a long decay chain. The three comparison results clearly establish the correctness of the analytical model and the accuracy and capability of the computer code.

3.2 Assessing physical and chemical parameters on the radionuclide plume migration

Physical processes and chemical reactions affect the extent of contaminant plumes, as well as concentration levels. To illustrate how the physical processes and chemical reactions affect multispecies plume development, we consider the four-member radionuclide decay chain used in the previous convergence test and solution verification. The model parameters are the same, except that the longitudinal (D_L) and transverse (D_T) dispersion coefficients are varied. Three sets of longitudinal and transverse dispersion coefficients D_L =1,000, D_T =100; D_L =1,000, D_T =200; D_L =2000, D_T =200 (all in m^2/year) are tested, all for a simulation time of 1,000 years.

Figure 9 illustrates the spatial concentration of four species at t = 1,000 year for the three sets of dispersion coefficients. The mobility of plumes of ^{234}U and ^{230}Th is retarded because of their stronger sorption ability. Hence the least retarded ^{226}Ra plume extensively migrated to 200 m × 60 m area

285 in the simulation domain, whereas the ^{234}U and ^{230}Th plumes are confined within 60 m × 50 m area

286 in the simulation domain. The moderate mobility of ^{238}Pu reflects the fact that it is a medial sorbed
287 member of this radionuclide decay chain. The high concentration level of ^{234}U accounts for the high
288 first-order decay rate constant of its parent species ^{238}Pu and its own low first-order decay rate constant.
289 The plume extents and concentration levels may be sensitive to longitudinal and transverse dispersion.
290 Increase of the longitudinal and/or transverse dispersion coefficients enhances the spreading of the
291 plume extensively along the longitudinal and/or transverse directions, thereby lowering the plume
292 concentration level. Because the concentration levels of the four radionuclides are influenced by both
293 source release rates and decay chain reactions, ^{230}Th has the least extended plume area, while ^{226}Ra
294 has the greatest plume area for all three set of dispersion coefficients. These dispersion coefficients
295 only affect the size of plumes of the four radionuclide, but the order of their relative plume size remains
296 the same (i.e. $^{226}Ra > {}^{238}Pu > {}^{234}U > {}^{230}Th$ for the simulated condition). Indeed, in the reactive
297 contaminant transport, the chemical parameters of sorption and decay rate are more important than the
298 physical parameters of dispersion coefficients that govern the order of the plume extents and the
299 concentration levels.
300
301 *3.3 Simulating the natural attenuation of chlorinated solvent plume migration*
302 Natural attenuation is the reduction in concentration and mass of the contaminant due to
303 naturally occurring processes in the subsurface environment. The process is monitored for regulatory
304 purposes to demonstrate continuing attenuation of the contaminant reaching the site-specific
305 regulatory goals within reasonable time, hence, the use of the term monitored natural attenuation
306 (MNA). MNA has been widely accepted as a suitable management option for chlorinated solvent
307 contaminated groundwater. Mathematical model are widely used to evaluate the natural attenuation
308 of plumes at chlorinated solvent sites. The multispecies transport analytical model developed in this

study provides an effective tool for evaluating performance of the monitoring natural attenuation of plumes at a chlorinated solvent site because a series of daughter products produced during biodegradation of chlorinated solvent such as *PCE→TCE→DCE→VC→ETH*. Thus simulation of the natural attenuation of plumes a chlorinated solvent constitutes an attractive field application example of our multispecies transport model.

A study of 45 chlorinated solvent sites by McGuire et al. (2014) found that mathematical models were used at 60% of these sites and that the public domain model BIOCHLOR (Aziz et al., 2000) provided by the Center for Subsurface Modeling Support (CSMoS) of USEPA was the most commonly used model. An illustrated example from BIOCHLOR manual (Aziz et al., 2000) is considered to demonstrate the application of the developed analytical model. This example application demonstrated that BIOCHLOR can reproduce plume movement from 1965 to 1998 at the contaminated site of Cape Canaveral Air Station, Florida. The simulation conditions and transport parameters for this example application are summarized in Table 10. Constant source concentrations rather than exponentially declining source concentration of five-species chlorinated solvents are specified in the $90.7\,m \le y \le 122.7\,m$ segment at the inlet boundary ($x = 0$). This means that the exponents (λ_{im}) of Bateman-type sources in Eqs. (16a) or (16b) need to be set to zero for the constant source concentrations and source intensity constants (b_{im}) are set to zero when subscript *i* does not equal to subscript *m.* Table 11 lists the coefficients of Bateman-type boundary source used for this example application involving the five-species dissolved chlorinated solvent problem. Spatial concentration contours of five-species at t = 1 year obtained from the derived analytical solutions for natural attenuation of chlorinated solvent plumes are depicted in Fig. 10. It is observed that the mobility of plumes is quite sensitive to the species retardation factors, whereas the decay rate constants determine the plume concentration level. The plumes can migrate over a larger region for species having a low retardation factor such as VC. The low decay rate constants such as ETH have

higher concentration distribution than the VC. It should be noted that a larger extent of plume observed for ETH in Fig. 10 is mainly attributed the plume mass accumulation from the predecessor species VC that have a larger plume extent. The effect of high retardation of the ETH is hindered by the mass accumulation of the predecessor species VC.

4. Conclusions

We present an analytical model with a parsimonious mathematical format for two-dimensional multispecies advective-dispersive transport of decaying contaminants such as radionuclides, chlorinated solvents and nitrogen. The developed model is capable of accounting for the temporal and spatial development of an arbitrary number of sequential first-order decay reactions. The solution procedures involve applying a series of Laplace, finite Fourier cosine and generalized integral transforms to reduce a partial differential equation system to an algebraic system, solving for the algebraic system for each species, and then inversely transforming the concentration of each species in transformed domain into the original domain. Explicit special solutions for Bateman type source problems are derived via the generalized analytical solutions. The convergence of the series expansion of the generalized analytical solution is robust and accurate. These explicit solutions and the computer code are comparing with the results computed by the numerical solutions. The two solutions agree well for a wide spectrum of concentration variations for three test examples. The analytical model is applied to assess the plume development of radionuclide and dissolved chlorinated solvent decay chain. The results show that dispersion only moderately modifies the size of the plumes, without altering the relative order of the plume sizes of different contaminant. It is suggested that retardation coefficients, decay rate constants and the predecessor species plume distribution mainly govern the order of plume size in groundwater. Although there are a number of numerical reactive transport models that can account for multispecies advective-dispersive transport, our analytical model with a computer code

that can directly evaluate the two-dimensional temporal-spatial concentration distribution of arbitrary target species without involving the computation of other species. The analytical model developed in this study effectively and accurately predicts the two-dimensional radionuclide and dissolved chlorinated plume migration. It is a useful tool for assessing the ecological and environmental impact of the accidental radionuclide releases such as the Fukushima nuclear disaster where multiple radionuclides leaked through the reactor, subsequently contaminating the local groundwater and ocean seawater in the vicinity of the nuclear plant. It is also a screening model that simulates remediation by natural attenuation of dissolved solvents at chlorinated solvent release sites. It should be noted the derived analytical model still has its application limitations. The model cannot handle the site with non-uniform groundwater flow or with multiple distinct zones. Furthermore, the developed model cannot simulate the more complicated decay chain problems such as diverging, converging and branched decay chains. The analytical model for more complicated decay chain problems can be pursued in the near future.

Appendix A

Derivation of analytical solutions

In this appendix, we elaborate on the mathematical procedures for deriving the analytical solutions.

The Laplace transforms of Eqs. (7a), (7b), (9)-(12) yield

$$\frac{1}{Pe_L}\frac{\partial^2 G_1(X,Y,s)}{\partial X^2}-\frac{\partial G_1(X,Y,s)}{\partial X}+\frac{\rho^2}{Pe_T}\frac{\partial^2 G_1(X,Y,s)}{\partial Y^2}-(R_1 s+\kappa_1)G_1(X,Y,s)=0 \tag{A1a}$$

$$\frac{1}{Pe_L}\frac{\partial^2 G_i(X,Y,s)}{\partial X^2}-\frac{\partial G_i(X,Y,s)}{\partial X}+\frac{\rho^2}{Pe_T}\frac{\partial^2 G_i(X,Y,s)}{\partial Y^2} \quad i=2,3,...N \tag{A1b}$$
$$-\kappa_i G_i(X,Y,s)+\kappa_{i-1}G_{i-1}(X,Y,s)=R_i s G_i(X,Y,s)$$

$$-\frac{1}{Pe_L}\frac{\partial G_i(X=0,Y,s)}{\partial X}+G_i(X=0,Y,s)=F_i(s)\left[H(Y-Y_1)-H(Y-Y_2)\right] \quad 0\le Y\le 1 \; i=1...N. \tag{A2}$$

$$\frac{\partial G_i(X=1,Y,s)}{\partial X}=0 \qquad 0\le Y\le 1 \qquad i=1...N. \tag{A3}$$

$$\frac{\partial G_i(X,Y=0,s)}{\partial Y}=0 \qquad 0\le X\le 1 \qquad i=1...N. \tag{A4}$$

$$\frac{\partial G_i(X,Y=1,s)}{\partial Y}=0 \qquad 0\le X\le 1 \qquad i=1...N. \tag{A5}$$

where s is the Laplace transform parameter, and $G_i(X,Y,s)$ and $F_i(s)$ are defined by the Laplace transformation relations as

$$G_i(X,Y,s)=\int_0^\infty e^{-sT}C_i(X,Y,T)dT \tag{A6}$$

$$F_i(s)=\int_0^\infty e^{-sT}f_i(T)dT \tag{A7}$$

The finite Fourier cosine transform is used here because it satisfies the transformed governing

391 equations in Eqs. (A1a) and (A2b) and their corresponding boundary conditions in Eqs. (A4) and (A5).

392 Application of the finite Fourier cosine transform on Eqs. (A1)-(A3) leads to

393 $$\frac{1}{Pe_L}\frac{d^2H_1(X,n,s)}{\partial X^2}-\frac{dH_1(X,n,s)}{dX}-\left(R_1 s+\kappa_1+\frac{\rho^2 n^2\pi^2}{Pe_T}\right)H_1(X,n,s)=0 \quad \text{(A8a)}$$

394 $$\frac{1}{Pe_L}\frac{d^2H_i(X,n,s)}{dX^2}-\frac{dH_i(X,n,s)}{dX}-\left(R_i s+\kappa_i+\frac{\rho^2 n^2\pi^2}{Pe_T}\right)H_i(X,n,s)+\kappa_{i-1}H_{i-1}(X,n,s)=0 \quad \text{(A8b)}$$

395 $$-\frac{1}{Pe_L}\frac{dH_i(X=0,n,s)}{dX}+H_i(X=0,n,s)=F_i(s)\Phi(n) \quad \text{(A9)}$$

396 $$\frac{dH_i(X=1,n,s)}{dX}=0 \quad \text{(A10)}$$

397 where $\Phi(n)=\begin{cases} Y_2-Y_1 & n=0 \\ \dfrac{\sin(n\pi Y_2)-\sin(n\pi Y_1)}{n\pi} & n=1,2,3... \end{cases}$, n is the finite Fourier cosine transform

398 parameter, $H_i(X,n,s)$ is defined by the following conjugate equations (Sneddon, 1972)

399 $$H_i(X,n,s)=\int_0^1 G_i(X,Y,s)\cos(n\pi Y)dY \quad \text{(A11)}$$

400 $$G_i(X,Y,s)=H_i(X,n=0,s)+2\sum_{n=1}^{n=\infty}H_i(X,n,s)\cos(n\pi Y) \quad \text{(A12)}$$

401 Using changes-of-variables, similar to those applied by Chen and Liu (2011), the advective terms
402 in Eqs. (A8a) and A(8b) as well as nonhomogeneous terms in Eq. (A9) can be easily removed. Thus,
403 substitutions of the change-of-variable into Eqs. (A8a), (A8b), (A9) and (A10) result in diffusive-type
404 equations associated with homogeneous boundary conditions

405 $$\frac{1}{Pe_L}\frac{d^2U_1(X,n,s)}{dX^2}-\left(R_1 s+\kappa_1+\frac{\rho^2 n^2\pi^2}{Pe_T}+\frac{Pe_L}{4}\right)U_1(X,n,s) = e^{-\frac{Pe_L}{2}X}\left(R_1 s+\kappa_1+\frac{\rho^2 n^2\pi^2}{Pe_T}\right)F_1(s)\Phi(n) \quad \text{(A13a)}$$

$$\frac{1}{Pe_L}\frac{d^2U_i(X,n,s)}{dX^2}-\left(\frac{Pe_L}{4}+R_i s+\kappa_1+\frac{\rho^2 n^2\pi^2}{Pe_T}\right)U_i(X,n,s)$$

$$=e^{-\frac{Pe_L}{2}X}\left(R_i s+\kappa_i+\frac{\rho^2 n^2\pi^2}{Pe_T}\right)F_i(s)\Phi(n)-e^{-\frac{Pe_L}{2}X}\kappa_{i-1}F_{i-1}(s)\Phi(n)-\kappa_{i-1}U_{i-1}(X,n,s) \quad \text{(A13b)}$$

$$-\frac{dU_i(X=0,n,s)}{dX}+\frac{Pe}{2}U_i(X=0,n,s)=0 \quad \text{(A14)}$$

$$\frac{dU_i(X=1,n,s)}{dX}+\frac{Pe_L}{2}U_i(X=1,n,s)=0 \quad \text{(A15)}$$

where $U_i(X,n,s)$ is defined as the following change-of-variable relation

$$H_i(X,n,s)=F_i(s)\Phi(n)+e^{\frac{Pe_L}{2}X}U_i(X,n,s) \quad \text{(A16)}$$

As detailed in Ozisik (1989), the generalized integral transform pairs for Eqs. (A13a) and (A13b) and its associated boundary conditions (A14) and (A15) are defined as

$$Z_i(\xi_l,n,s)=\int_0^1 K(\xi_l,X)U_i(X,n,s)dX \quad \text{(A17)}$$

$$U_i(X,n,s)=\sum_{l=1}^{\infty}\frac{K(\xi_l,X)}{N(\xi_l)}Z_i(\xi_l,n,s) \quad \text{(A18)}$$

where $K(\xi_l,X)=\frac{Pe_L}{2}\sin(\xi_l X)+\xi_l\cos(\xi_l X)$ is the kernel function, $N(\xi_l)=\frac{2}{\frac{Pe_L^2}{4}+Pe_L+\xi_l^2}$,

ξ_l is the eigenvalue, determined from the equation

$$\xi_l\cot\xi_l-\frac{\xi_l^2}{Pe_L}+\frac{Pe_L}{4}=0 \quad \text{(A19)}$$

The generalized integral transforms of Eqs. (13a) and (13b) give

$$-\left(R_1 s+\kappa_1+\frac{\rho^2 n^2\pi^2}{Pe_T}+\frac{Pe_L}{4}+\frac{\xi_l^2}{Pe_L}\right)Z_i(\xi_l,n,s)=\left(R_1 s+\kappa_1+\frac{\rho^2 n^2\pi^2}{Pe_T}\right)F_1(s)\Phi(n)\Theta(\xi_l) \quad \text{(A20)}$$

$$-\left(R_i s+\kappa_i+\frac{\rho^2 n^2 \pi^2}{Pe_T}+\frac{Pe_L}{4}+\frac{{\xi_l}^2}{Pe_L}\right)Z_i(\xi_l,n,s)$$

$$=\left(R_i s+\kappa_i+\frac{\rho^2 n^2 \pi^2}{Pe_T}\right)F_i(s)\Phi(n)\Theta(\xi_l)-\kappa_{i-1}F_{i-1}(s)\Phi(n)\Theta(\xi_l)-\kappa_{i-1}Z_{i-1}(\xi_l,n,s) \quad \text{(A21)}$$

where $\Theta(\xi_l)=\dfrac{Pe_L\xi_l}{\dfrac{{Pe_L}^2}{4}+{\xi_l}^2}$.

Solving for Eqs. (A20) and (A21) algebraically for each species, $Z_i(\xi_l,n,s)$, in sequence, leads to

$$Z_1(\xi_l,n,s)=-\frac{s+\alpha_1-\beta_1}{s+\alpha_1}F_1(s)\Phi(n)\Theta(\xi_l) \quad \text{(A22)}$$

$$Z_2(\xi_l,n,s)=\left[-\frac{s+\alpha_2-\beta_2}{s+\alpha_2}F_2(s)+\frac{\sigma_2\beta_1}{(s+\alpha_2)(s+\alpha_1)}F_1(s)\right]\Phi(n)\Theta(\xi_l) \quad \text{(A23)}$$

$$Z_3(\xi_l,n,s)=\left[-\frac{s+\alpha_3-\beta_3}{s+\alpha_3}F_3(s)+\frac{\sigma_3\beta_2}{(s+\alpha_3)(s+\alpha_2)}F_2(s)\right.$$
$$\left.\frac{\sigma_3\sigma_2\beta_1}{(s+\alpha_3)(s+\alpha_2)(s+\alpha_1)}F_1\right]\Phi(n)\Theta(\xi_l) \quad \text{(A24)}$$

$$Z_4(\xi_l,n,s)=\left[-\frac{s+\alpha_4-\beta_4}{s+\alpha_4}F_4(s)+\frac{\sigma_4\beta_3}{(s+\alpha_4)(s+\alpha_3)}F_3(s)\right.$$
$$\left.+\frac{\sigma_4\sigma_3\beta_2}{(s+\alpha_4)(s+\alpha_3)(s+\alpha_2)}F_2(s)+\frac{\sigma_4\sigma_3\sigma_2\beta_1}{(s+\alpha_4)(s+\alpha_3)(s+\alpha_2)(s+\alpha_1)}F_1(s)\right]\Phi(n)\Theta(\xi_l) \quad \text{(A25)}$$

where $\alpha_i(\xi_l)=\dfrac{\kappa_i}{R_i}+\dfrac{\rho^2 n^2\pi^2}{Pe_T R_i}+\dfrac{Pe_L}{4R_i}+\dfrac{{\xi_l}^2}{Pe_L R_i}$, $\beta_i(\xi_l)=\dfrac{Pe_L}{4R_i}+\dfrac{{\xi_l}^2}{Pe_L R_i}$, $\sigma_i=\dfrac{\kappa_{i-1}}{R_i}$.

Upon inspection of Eqs. (A22)-(A25), compact expressions valid for all species can be generalized as

$$Z_i(\xi_l,n,s)=\left[P_i(\xi_l,n,s)+Q_i(\xi_l,n,s)\right]\Phi(n)\Theta(\xi_l) \quad i=1,2...N \quad \text{(A26)}$$

where $P_i(\xi_l,n,s) = -\dfrac{s+\alpha_i-\beta_i}{s+\alpha_i}F_i(s)$ and $Q_i(\xi_l,n,s) = \sum_{k=0}^{k=i-2} \dfrac{\beta_{i-k-1}\prod_{j_1=0}^{j_1=k}\sigma_{i-j_1}}{\prod_{j_2=0}^{j_2=k+1}\left(s+\alpha_{i-j_2}\right)}F_{i-k-1}(s)$.

The solutions in the original domain are obtained by a series of integral transform inversions in combination with changes-of-variables.

The inverse generalized integral transform of Eq. (A26) gives

$$W_i(X,n,s) = \sum_{m=1}^{\infty} \frac{K(\xi_l,X)}{N(\xi_l)}\left[P_i(\xi_l,n,s)+Q_i(\xi_l,n,s)\right]\Phi(n)\Theta(\xi_l) \tag{A27}$$

Using change-of-variable relation of Eq. (A16), one obtains

$$H_i(\xi_l,n,s) = F_i(s)\Phi(n) + e^{\frac{Pe_L}{2}x_D}\sum_{m=1}^{\infty}\frac{K(\xi_l,x_D)}{N(\xi_l)}\left[P_i(\xi_l,n,s)+Q_i(\xi_l,n,s)\right]\Phi(n)\Theta(\xi_l) \tag{A28}$$

The finite Fourier cosine inverse transform of Eq. (A28) results in

$$\begin{aligned} &G_i(X,Y,s) \\ &= F_i(s)\Phi(n=0) + e^{\frac{Pe_L}{2}X}\cdot\sum_{l=1}^{\infty}\frac{K(\xi_l,X)}{N(\xi_l)}\left[P_i(\xi_l,n,s)+Q_i(\xi_l,n,s)\right]\Phi(n=0)\Theta(\xi_l) \\ &+2\sum_{n=1}^{n=\infty}\left\{F_i(s)\Phi(n)+e^{\frac{Pe_L}{2}X}\sum_{l=1}^{\infty}\frac{K(\xi_l,X)}{N(\xi_l)}\left[P_i(\xi_l,n,s)+Q_i(\xi_l,n,s)\right]\Phi(n)\Theta(\xi_l)\right\}\cos(n\pi Y) \end{aligned} \tag{A29}$$

The analytical solutions in the original domain will be completed by taking the Laplace inverse transform of Eq. (A29). $P_i(\xi_l,n,s)$ in Eq. (29) is in the form of the product of two functions . The Laplace transform of $\dfrac{s+\alpha_i-\beta_i}{s+\alpha_i}$ can be easily obtained as

$$L^{-1}\left[\frac{s+\alpha_i-\beta_i}{s+\alpha_i}\right] = \delta(T) - \beta_i e^{-\alpha_i T} \tag{A30}$$

Thus, the Laplace inverse of $P_i(\xi_l,n,s)$ can be achieved using the convolution theorem as

$$p_i(\xi_l, n, T) = L^{-1}\left[P_i(\xi_l, n, s)\right] = L^{-1}\left[-\frac{s+\alpha_i-\beta_i}{s+\alpha_i}F_i(s)\right] = -f_i(T) + \beta_i e^{-\alpha_i T}\int_0^T f_i(\tau)e^{\alpha_i \tau}d\tau \qquad \text{(A31)}$$

The Laplace inverse of $Q_i(\xi_l, n, s)$ can be also approached using the similar method. By taking Laplace inverse transform on $Q_i(\xi_l, n, s)$, we have

$$q_i(\xi_l, n, T) = L^{-1}\left[Q_i(\xi_l, n, s)\right] = L^{-1}\left[\sum_{k=0}^{k=i-2}\frac{\beta_{i-k-1}\prod_{j_1=0}^{j_1=k}\sigma_{i-j_1}}{\prod_{j_2=0}^{j_2=k+1}\left(s+\alpha_{i-j_2}\right)}F_{i-k-1}(s)\right]$$

$$= \sum_{k=0}^{k=i-2}\beta_{i-k-1}\prod_{j_1=0}^{j_1=k}\sigma_{i-j_1}L^{-1}\left[\frac{1}{\prod_{j_2=0}^{j_2=k+1}\left(s+\alpha_{i-j_2}\right)}F_{i-k-1}(s)\right] \qquad \text{(A32)}$$

Expressing $\frac{1}{\prod_{j_2=0}^{j_2=k+1}\left(s+\alpha_{i-j_2}\right)}$ as the summation of partial fractions and applying the inverse Laplace transform formula, one gets

$$L^{-1}\left[\frac{1}{\prod_{j_2=0}^{j_2=k+1}\left(s+\alpha_{i-j_2}\right)}\right] = L^{-1}\left[\sum_{j_2=0}^{j_2=k+1}\frac{1}{\prod_{j_3=i-k-1, j_3\neq i-j_2}^{j_3=i}(\alpha_{j_3}-\alpha_{i-j_2})\left(s+\alpha_{i-j_2}\right)}\right]$$

$$= \sum_{j_2=0}^{j_2=k+1}\frac{e^{-\alpha_{i-j_1}T}}{\prod_{j_3=i-k-1, j_3\neq i-j_1}^{j_3=i}(\alpha_{j_3}-\alpha_{i-j_1})} \qquad \text{(A33)}$$

Recall that the inverse Laplace transform of $F_{i-k-1}(s)$ is $f_{i-k-1}(T)$. Thus, the Laplace inverse

transform of $\frac{1}{\prod_{j_2=0}^{j_2=k+1}\left(s+\alpha_{i-j_2}\right)}F_{i-k-1}(s)$ in Eq. (1) can be achieved using the convolution integral equation as

$$L^{-1}\left[\frac{1}{\prod_{j_2=0}^{j_2=k+1}\left(s+\alpha_{i-j_2}\right)}F_{i-k-1}(s)\right]=\sum_{j_2=0}^{j_2=k+1}\frac{e^{-\alpha_{i-j_1}T}\int_0^T e^{\alpha_{i-j_1}\tau}f_{i-k-1}(\tau)d\tau}{\prod_{j_3=i,\ j_3=i-k-1,\ j_3\neq i-j_2}^{j_3=i}\left(\alpha_{j_3}-\alpha_{i-j_2}\right)} \tag{A34}$$

Putting Eq. (A34) into Eq. (A2) we can obtain the following form:

$$q_i(\xi_l,n,T)=\sum_{k=0}^{k=i-2}\beta_{i-k-1}\prod_{j_1=0}^{j_1=k}\sigma_{i-j_1}\sum_{j_2=0}^{j_2=k+1}\frac{e^{-\alpha_{i-j_1}T}\int_0^T e^{\alpha_{i-j_1}\tau}f_{i-k-1}(\tau)d\tau}{\prod_{j_3=i,\ j_3=i-k-1,\ j_3\neq i-j_2}^{j_3=i}\left(\alpha_{j_3}-\alpha_{i-j_2}\right)} \tag{A35}$$

Thus, the final solution can be expressed as Eq.(13) with the corresponding functions defined in Eqs.(14) and (15).

Note that Eq. (A33) is invalid for some of α_{i-j_2} being identical. For such conditions, we can still reduce $\frac{1}{\prod_{j_2=0}^{j_2=k+1}\left(s+\alpha_{i-j_2}\right)}$ to a sum of partial fraction expansion. However, it will lead to different Laplace inverse formulae. For example, the following formulae is used for all α_{i-j_2} being identical

$$L^{-1}\left[\frac{1}{\prod_{j_2=0}^{j_2=k+1}\left(s+\alpha_{i-j}\right)}\right]=\frac{T^k e^{-\alpha_{i-j_2}T}}{k!} \tag{A36}$$

The generalized formulae for the cases with some of α_{i-j_2} being identical will not be provided

herein because there are a large number of combinations of α_{i-j_2}. We suggest that the readers can pursue the solutions by following the similar steps for such specific conditions case by case.

588 **Table 1**

589 Transport parameters used for convergence test example 1 involving the four-species radionuclide
590 decay chain problem used by van Genuchten (1985)

Parameter	Value
Domain length, L [m]	250
Domain width, W [m]	100
Seepage velocity, v [m year^{-1}]	100
Longitudinal Dispersion coefficient, D_L [m^2 year^{-1}]	1,000
Transverse Dispersion coefficient, D_T [m^2 year^{-1}]	100
Retardation coefficient, R_i	
^{238}Pu	10,000
^{234}U	14,000
^{230}Th	50,000
^{226}Ra	500
Decay constant, k_i [year^{-1}]	
^{238}Pu	0.0079
^{234}U	0.0000028
^{230}Th	0.0000087
^{226}Ra	0.00043
Source decay constant, λ_m [year^{-1}]	
^{238}Pu	0.0089
^{234}U	0.00100280
^{230}Th	0.00100870
^{226}Ra	0.00143

591

592

Table 2

Values for coefficients of Bateman-type boundary source for four-species transport problem used by van Genuchten (1985)

Species, *i*	b_{im}			
	m=1	*m=2*	*m=3*	*m=4*
^{238}Pu , *i=1*	1.25			
^{234}U , *i=2*	-1.25044	1.25044		
^{230}Th , *i=3*	0.443684×10^{-3}	0.593431	-0.593874	
^{226}Ra , *i=4*	-0.516740×10^{-6}	0.120853×10^{-1}	-0.122637×10^{-1}	0.178925×10^{-3}

598 **Table 3**

599 Solution convergence of each species concentration at transect of inlet boundary ($x = 0$) for four-
600 species radionuclide transport problem considering simulated domain of $L = 250$ m, $W = 100$ m,
601 subject to Bateman-type sources located at $40\,m \le y \le 60\,m$ for t = 1,000 year (M = number of
602 terms summed for inverse generalized integral transform; N = number of terms summed for inverse
603 finite Fourier cosine transform). When we investigate the required M for inverse generalized integral
604 transform, N=16,000 for the finite Fourier cosine transform inverse are used. When we investigate the
605 required N for inverse finite Fourier cosine transform, M=1,600 for the generalized transform inverse
606 are used.

Table 5

Solution convergence of each species concentration at transect of exit boundary ($x = 250$ m) for four-species radionuclide transport problem considering simulated domain of $L = 250$ m, $W = 100$ m subject to Bateman-type sources located at $40\,m \le y \le 60\,m$ for t = 1000 year (M = number of terms summed for inverse generalized integral transform and N = number of terms summed for inverse finite Fourier cosine transform). When we investigate the required M for inverse generalized integral transform, N=16 for the finite Fourier cosine transform inverse are used. When we investigate the required N for inverse finite Fourier cosine transform, M=6,400 for the generalized transform inverse are used.

Figures Captions

Fig. 1. Schematic representation of two-dimensional transport of decaying contaminants in a uniform flow field with flux boundary source located at of the inlet boundary.

Fig. 2. Comparison of spatial concentration profiles of four species along the longitudinal direction (=50 m) at t = 1,000 years obtained from derived analytical solutions and numerical solutions for convergence test example 1 of four-member radionuclide decay chain $^{238}Pu \rightarrow ^{234}U \rightarrow ^{230}Th \rightarrow ^{226}Ra$.

Fig. 3. Comparison of spatial concentration profiles of four species along the transverse direction (=0 m) at t = 1,000 years obtained from derived analytical solutions and numerical solutions for convergence test example 1 of four-member radionuclide decay chain $^{238}Pu \rightarrow ^{234}U \rightarrow ^{230}Th \rightarrow ^{226}Ra$.

Fig. 4. Comparison of spatial concentration profiles of four species along the transverse direction (=25 m) at t = 1,000 years obtained from derived analytical solutions and numerical solutions for convergence test example 1 of four-member radionuclide decay chain $^{238}Pu \rightarrow ^{234}U \rightarrow ^{230}Th \rightarrow ^{226}Ra$.

Fig. 5. Comparison of spatial concentration profiles of four species along the longitudinal direction (=50 m) at t = 1,000 years obtained from derived analytical solutions and numerical solutions for convergence test example 2 of four-member radionuclide decay chain $^{238}Pu \rightarrow ^{234}U \rightarrow ^{230}Th \rightarrow ^{226}Ra$.

Fig. 6. Comparison of spatial concentration profiles of four species along the transverse direction (=0

724 m) at t = 1,000 years obtained from derived analytical solutions and numerical solutions
725 for convergence test example 2 of four-member radionuclide decay chain
726 $^{238}Pu \rightarrow ^{234}U \rightarrow ^{230}Th \rightarrow ^{226}Ra$.

727 Fig. 7. Comparison of spatial concentration profiles of four species along the transverse direction
728 (=25 m) at t = 1,000 years obtained from derived analytical solutions and numerical
729 solutions for convergence test example 2 of four-member radionuclide decay chain
730 $^{238}Pu \rightarrow ^{234}U \rightarrow ^{230}Th \rightarrow ^{226}Ra$.

731 Fig. 8. Comparison of spatial concentration profiles of ten-species along x-direction at t = 20 days
732 obtained from derived analytical solutions and numerical solutions for the test example 3
733 of ten species decay chain used by Srinivasan and Clement (2008b).

734 Fig. 9. Effects of physical processes and chemical reactions on the concentration contours of four-
735 species at t = 1,000 years obtained from derived analytical solutions for four-member decay
736 chain $^{238}Pu \rightarrow ^{234}U \rightarrow ^{230}Th \rightarrow ^{226}Ra$.

737 Fig. 10. Spatial concentration contours of five-species at t = 1 year obtained from derived analytical
738 solutions for natural attenuation of chlorinated solvent plumes $PCE \rightarrow TCE \rightarrow DCE \rightarrow VC$
739 $\rightarrow ETH$.
