

Interactive comment on “Snow distribution over the Namco lake area of the Tibetan Plateau” by M. Li et al.

M. Malik (Referee)

malik14406@itc.nl

Received and published: 19 May 2009

General Comments: The work presented in the paper is good for understanding the lake effect snow and it is worthful for publishing after some modifications. The phenomena of lake effect snow discussed in the paper for Namco Lake area needs to be investigated and/or presented in more details. Because the results presented here lack in describing the physical processes involved in lake effect snow for Namco lake area. Furthermore, the results need to be validated. For this, some comments have been suggested in the following document. English and terminologies of the paper need to be improved.

1) Does the paper address relevant scientific questions within the scope of HESS? Yes

Discussion Paper

2) Does the paper present novel concepts, ideas, tools, or data? The literature review part in the paper is weak. It does not give clear view on what has been discussed in the past research for modeling lake effect snow. What methods and data have been used/explored in the previous research? What limitations have been pointed out in modeling this effect? How these limitations have been addressed in the study? And why the combination of WRF and NOAA has been selected for this study.

3) Are substantial conclusions reached? The conclusion of the study needs to be improved. For suggestions, please refer questions 5 and 10.

4) Are the scientific methods and assumptions valid and clearly outlined? The method that has been used to study the phenomena is not outlined clearly. The setup of the models, discretization of the model domain have not been discussed in details. It is also not mentioned clearly why the terminologies of control and sensitive experiments have been used in the study and what is the main difference in both modeling approaches. From the paper, it seems that only the difference between the two experiments is the observation of lake surface temperature. In the sensitive experiment remotely sensed lake surface temperature has been used but it is not mentioned how the lake surface temperature has been retrieved from the brightness temperatures, which sensor or product has been used. How these remote sensing observations have been used and how the scaling issues have been addressed in the study. A brief explanation is also required on how the snow distribution over the model domain has been simulated using WRF and NOAA.

5) Are the results sufficient to support the interpretations and conclusions? The main objective of the paper is to simulate distribution of lake effect snow on Namco lake area. Therefore, it will be better to validate the simulated amount and coverage of snow for both the experiments. For this purpose, remote sensing snow products could be explored. From this study the only conclusion that can be drawn is that the accumulation of snow is more on lee shore in both the experiments. But whether this conclusion is right or wrong we cannot comment on it. We also cannot say which simulation con-

trol or sensitive is better. The comparison of the simulated and observed temperature, wind speed and direction need to be discussed in more details.

6) Is the description of experiments and calculations sufficiently complete and precise to allow their reproduction by fellow scientists (traceability of results)? From the text, it is very difficult to reproduce/apply the approach presented in the paper to produce comparable results. The method need to be precisely described. Detailed description is needed for what and how different datasets have been used. For details please refer question no 4.

7) Do the authors give proper credit to related work and clearly indicate their own new/original contribution? Please refer question no 2.

8) Does the title clearly reflect the contents of the paper? Yes

9) Does the abstract provide a concise and complete summary? Overall structure of the abstract is ok. But the results (from line number 7 to 12) can be improved for better and precise readability. Please refer minor comments.

10) Is the overall presentation well structured and clear? Regarding the structure of the paper, it will be good if the study area and datasets used in the study should be presented before Model description and experimental design. Study area needs a bit more explanation on geographic setting, topography, and then it will help in understanding the discretization of the model domain. The heading '“Results”' on page 848 could be written as '“Results and Discussion”'. Whereas the heading '“Summary and discussion”' on page 850 could be replaced with '“Conclusions”'. In the conclusion/summary, it will be more effective if a take home message is presented.

11) Is the language fluent and precise? The language needs to be improved, especially the grammar and use of correct terminologies as indicated in the minor comments.

12) Are mathematical formulae, symbols, abbreviations, and units correctly defined and

used? The unit of mixing rate of snow; in Fig 5 on page 856 needs to be checked or explained.

13) Should any parts of the paper (text, formulae, figures, tables) be clarified, reduced, combined, or eliminated? Few comments on the figures can be referred to in the minor comments.

14) Are the number and quality of references appropriate? More references are required in the text on page 845. Please have a look on minor comments.

15) Is the amount and quality of supplementary material appropriate? NA

Minor comments: Page 844 Line 11: "Modified" is not appropriate term here, because in the text skin temperature has been retrieved from remote sensing. Line 12: Skin temperature is a state variable Line 19: Factors: What are these factors? Line 19: maintenance of Asian summer Line 26: maintenance of the Tibetan High or Asian monsoon

Page 845 Line 6: from the lower to the upper? Please explain Line 6: please put references here for evidences Line 7: Snow cover and snow depth are two separate state variables. We can write snow depth/snow water equivalent but not snow cover/snow depth Line 10: references? what these studies show and how is you study differs from them? Line 16: In this study, lake effect snow is analyzed using WRF model Line 19: lake surface temperatures are compared Line 19: what is base simulation? it has not been discussed in the methodology Line 24: is used in this study. Line 26: helping verb is required

Page 846 Line 8: The snow model of Noah LSM has only one layer of snow and simulates Line 11: skin temperature is a state variable Line 12: Detailed scheme and physical processes Line 13: model are described by former literature

Page 847 Line 3: skin temperature is always 300K. This is interesting please explain? Line 3: see below. Never use soft referencing
