Received and published: 3 August 2011

First, we would like to thank the reviewer for his/her comment/suggestion since they have contributed to improve the paper. Appropriate changes have been made following each one of the reviewer’s comments/suggestions. In the following, detailed and justified responses, as well as the corresponding modifications into the manuscript (with appropriate reference to particular page and line numbers) are given.

Answer to Comments:

surface moisture conditions, and therefore not applicable to small fields.

Following this referee comment a new paragraph has been added (page 3, line 9): “A dry or “hot” pixel, where LE is assumed to be zero, and a wet or “cold” pixel, where H is expected to be zero, are required. Due to the difficulty to bring together these two extreme conditions, SEBAL is not applicable to small crop fields (Bastiaansen et al. 1998).”

Study site and materials The final height of the sorghum is nearly 5 m! What do you think the rooting depth is? Is the lysimeter deep enough to account for the depth of the roots?

Maximum root depth for a sweet sorghum crop can oscillate between 1-2 m (Allen et al., 1998). However, in the lysimeter plot, the rooting growth is limited by the average soil depth (around 0.4 m), because of the development of a more or less fragmented petrocalcic horizon. Therefore, the lysimeter deep (1.7 m) is enough to account for the depth of the roots (no more than 0.4-0.5 m).

Model description Please explain why it is necessary to make a distinction between r_{ah} and r_{a0} , and then how they are different. Specific mathematical expressions are needed for each. In the Norman et al. paper they are the same. From your definitions of the two variables, they seem to be the same to me. Distinction between r_{ah} and r_{a0} is made because (page 7, line 16): “. . .transport of heat and momentum is not equally efficient over the canopy (Sánchez et al. 2008)”. Also, as stated in the text (page 7, line 7): “ r_{ah} is the aerodynamic resistance to heat transfer between the canopy and the reference height at which the atmospheric data are measured ($s\ m^{-1}$), r_{a0} is the aerodynamic resistance to heat transfer between the point $z_0 + d$ (z_0 : canopy roughness length for momentum, d : displacement height) and the reference height ($s\ m^{-1}$).”. The point $z_0 + d$ differs from the canopy height. The authors believe that including here further considerations at this point could mislead the reader. For this reason, the reader is referred to the paper containing all details about the model

scheme and equations.

In (7) the sky does not fill the entire upper hemisphere that the soil "sees." A large fraction of this hemisphere, when the vegetation fraction P_v is greater than about 0.5, is occupied by the vegetation canopy. Longwave emission from the vegetation canopy could be much higher than the longwave emission from the sky, especially on clear days. Please explain why you can neglect emission from the vegetation that is incident on the soil surface.

We agree with the referee that in the soil-canopy-atmosphere system there can be also interaction between the soil and canopy components, and emissions from the vegetation may affect energy balance in the soil in the same way that emissions from this soil may affect energy balance for the canopy. However, the reader should note that according to STSEB scheme basis no direct coupling is allowed between soil and vegetation (Sánchez et al. 2008). In this sense this model is similar to a patch approach, and for this reason a weighting of the soil and canopy elements using their respective occupation partial areas is introduced instead.

A new sentence has been inserted (page 7, line 29): "Note that longwave emission from one component over the other is not accounted since no direct coupling is considered between soil and vegetation in the STSEB scheme (Sánchez et al. 2008)." This sentence adds to another already included in the text (page 8, line 6): "According to this framework, a complete and independent energy balance between the atmosphere and each component of the surface is established, from the assumption that all the fluxes act vertically".

3946:14 Please explain what the "effective emissivity" is. I assume it is the surface emissivity, but it should be clearly stated.

Yes, this is the "effective surface emissivity", first introduced in equation (2).

3946:17-20 This sentence needs to be rewritten, I do not understand it in its current
