

Interactive comment on “Technical Note: Multiple wavelet coherence for untangling scale-specific and localized multivariate relationships in geosciences” by W. Hu and B. C. Si

W. Hu and B. C. Si

wei.hu@plantandfood.co.nz

Received and published: 25 June 2016

General Comments The multiple wavelet coherence methodology presented in the manuscript by Hu and Si represents an important contribution to wavelet analysis. In particular, Hu and Si build upon the previous work of Ng and Chan (2012) to extend multiple wavelet coherence to case of more than two predictor variables. The authors further demonstrate that the new multiple wavelet coherence methodology is better suited for situations where the predictor variables are cross-correlated. The problems with the traditional formulation are clearly stated and consistent with the objective of the paper proposed in the introduction section. Theoretical examples were also presented to highlight the advantages of the new methodology relative to existing ones. I their

recommend that the manuscript be accepted after the substantial correction of grammatical errors and the consideration of more specific comments presented below.

Response:

Thank you for the positive comments.

Specific comments The conclusion section simply summarizes the results of the paper. The authors could consider expanding the conclusion section into a discussion section to comment on limitations of the method. After all, wavelet analysis, while useful, is not a scientific panacea. More specifically, the inclusion of more predictor variables may result in the statistical significance threshold at a particular wavelet scale and time to approach unity, which would impose a limit on how much statistical information can be gained. This phenomenon occurs with the traditional multiple wavelet coherence formulation, where the threshold for 5

Response: We agree with you that one of the limitation is that the critical values increase with the number of predictor variables. This is also why the percentage area of significant coherence (PASC) for three predictor variables (z_2 , z_4 , and noised z_4) are even lower than for only two predictor variables (z_2 and z_4) when the third predictor variable (noised z_4) is not statistically significant to explain the variation of the response variable. Please see Lines 265-266 in the attached revision. We put this limitation in the conclusion part as "Theoretically, any number of predictor variables can be included in the multiple wavelet analysis. However, the statistical significance threshold usually increases with the number of the predictor variables (Grinsted et al., 2004; Ng and Chan, 2012a), and inclusion of too many predictor variables may result in the statistical significance threshold at particular wavelet scales (e.g., the lowest and largest scales) to approach unity. This would restrict the availability of statistical information." (Lines 391-397 in the attached revision).

The author may also consider discussing at least briefly the problem of simultaneously testing multiple statistical hypothesis, as discussed in Maraun and Kurths (2004),

Discussion paper

Maraun et al. (2007), Schulte et al. (2015), and Schulte (2016). Multiple-testing problem is a major problem in wavelet analysis and therefore merits consideration in a discussion section. Presenting clearly the methodological limitations will better guide the likely interdisciplinary readership in making decisions regarding what analysis tools to implement.

Response: The multiple-testing problem has been briefly discussed in the conclusion part. "In addition, similar to bivariate wavelet analysis, the new method also suffers from the multiple-testing problem (Maraun and Kurths, 2004; Maraun et al., 2007; Schulte et al., 2015; Schulte, 2016). Therefore, a more robust statistical significance testing method may be beneficial to the new method." (Lines397-400 in the attached revision).

Throughout the manuscript, the authors mention how geoscience data are often nonstationary. Perhaps the term is used too loosely in some instances and is sometimes inconsistent with the strict time series analysis definition. Even white and red-noise processes contain time and scale-localized features in wavelet space, even though their respective statistics are stationary at all orders. Time- and scale-localized features are evident in the wavelet power spectrum of say, the North Atlantic Oscillation (NAO), even though the statistics of the NAO are consistent with a first-order Markov process (Feldstein, 2000). Therefore, in some instances, I recommend changing the word "nonstationary" to "transient" or "transitory".

Response: We agree. In the introduction, we made this more clear as "More often than not, geoscience data are transient, consisting of a variety of frequency regimes that may be localized in space or time (Torrence and Compo, 1998; Si and Zeleke, 2005; Graf et al., 2014). The transient characteristics exist widely in non-stationary but also sometimes in stationary processes (Feldstein, 2000)." (Lines35-39 in the attached revision). At many instances, we changed the "non-stationary" to "transient" when suitable, such as Line 41, 59, 67 in the attached revision.

Some Technical Corrections Page 2 Line 3536. Change “geoscience data is” to “geoscience data are”.

Response: Yes, done at L36.

Page 2 Line 39. Is it better to say bivariate wavelet coherency rather than “simple wavelet coherency”

Response: Yes, we changed all throughout the paper.

Page 5, Line 97. Add comma before “respectively”.

Response: Yes, we did throughout the paper.

Page 9, Line 169-171. The sentence can be slightly simplified by changing “white noise with a mean of 0” to “zero-mean white noise”. Perhaps it is redundant to write that the white noise processes were generated. Authors could consider just saying that white noise was added to the predictor variables.

Response: We agree. Now, it changed to “zero-mean white noises with a mean of 0 and standard deviations of 0.3, 1, and 4 are added to the predictor variables of y_2 (or z_2) and y_4 (or z_4)”.

Page 9, Lines 171-173. The sentence “The resulting noised series are termed weakly, moderately, 172 and highly noised series respectively, and have a correlation coefficient of 0.9, 0.5, 173 and 0.1 respectively, with their original predictor variable” needs to be rewritten and simplified. Consider breaking the sentence into two separate sentences.

Response: We changed it to two sentences. Now, it looks like “The resulting noised series have correlation coefficients of 0.9, 0.5, and 0.1, respectively, with their original predictor variable. Therefore, we will refer them to weakly, moderately, and highly noised series, respectively.” (Lines 177-180 in the attached revision copy).

The authors should carefully check for grammatical errors and make similar changes

throughout the manuscript.

Response: Yes, done. Further English check will be made if a chance for revision will be given.
