

RESPONSE TO REVIEWER 3 COMMENTS

Performance of bias correction schemes for CMORPH rainfall estimates in the Zambezi River Basin

Webster Gumindoga^{1,2}, Tom H. M. Rientjes¹, Alemseged T. Haile³, Hodson Makurira², and Paolo Reggiani⁴

Comment by reviewer

The authors have responded to all comments, and most of the concerns raised by the referees were accordingly addressed. On one hand, I consider that this manuscript presents a cutting edge case study, which is very straightforward and potentially beneficial to other studies in this region.

Response by authors

We thank the reviewer for the positive compliment and for finding merit in our manuscript.

Comment by reviewer

On the other hand, I still found the manuscript weak in some parts. The main aspect, as referee #2 pointed out, is that the discussion is missing content.

Response by authors

The authors have separated results section from discussion and added further content to the discussion.

Comment by reviewer

To that end, I have some comments and suggestions:

1. The manuscript is not convincing – and probably redundant – in dealing with the effects of open water bodies on the performance of CMORPH rainfall. To support open water bodies' criterion, the manuscript only uses a relatively vague statement with two supporting references (L119-121). In fact, one of these references (Rientjes et al., 2013, DOI: 10.1016/j.jag.2012.07.009) is not actually a study that assesses the effects of water bodies on rainfall patterns and, therefore, not a suitable reference to support the demand for such analysis.

34 **Response by authors**

35 Following the recommendation by reviewer, the authors revisited descriptions on the effect of
36 large scale open water bodies. We also revisited the analysis. To some extent we understand
37 the reviewer's statement on redundancy and agree effects of elevation and distance to water
38 bodies may be co-correlated and thus isolated effects are difficult to show. On the other hand
39 we disagree that, by the redundancy claim, our findings are not relevant and thus should be
40 omitted. Our findings show that effects of distances larger than 10 km are minimal but finding
41 sin Taylor diagram show that errors between gauge and SRE increases at shorter distances (<
42 10 km). As such it appears that SRE deviate more from gauge observations at distances close
43 (<10 km) to a large water body. In the manuscript we stipulate that findings only are site
44 specific and do not allow generalisation since the gauge network has some constrains in terms
45 of density and limited number of gauges at short distances. We think findings are relevant for
46 researches in the work field who assess performance of SREs, we do not want to withhold the
47 results that by itself are valuable to stimulate further research on the subject to assess causes of
48 SRE bias.

49

50 The comment by the reviewer on the Haile et al. (2009) and Rientjes et al. (2013) paper is
51 somewhat strange since those studies do not serve to provide some relatively vague statement
52 on the effects of water bodies on rainfall patterns. The claim that references are not suitable to
53 support the demand for our analysis is surprising. We agree that in both studies the main
54 research objective was not to identify effects of distance to large scale open water bodies in the
55 Upper Blue Nile basin but saw enough evidence in the research findings to publish results.
56 Both papers are in respected journals and were peer reviewed with approval to publish findings
57 on lake distance effects. We wonder why the reviewer claims that only main research outcomes
58 are worth to be noted and to be further investigated although much research is triggered by less
59 prominent findings.

60

61 **Comment by reviewer**

62 The study concludes (L842-846) that the CMORPH estimate has the largest mismatches in two
63 situations: at low elevation and in close proximity to open water bodies. Considering that the
64 water bodies selected in this study are actually in the relatively low elevation zones of this
65 watershed, I wonder how redundant this analysis is by considering the terrestrial elevation and
66 the distance to the water bodies separately.

67 The effect of large water surfaces has consequences to the climate, the time response and scale
68 follow very complex dynamics that probably could not be addressed solely by the effect of one
69 parameter (distance to the water body). To that end, I recommend either removing the bias
70 analysis that considers the distance to the water bodies or, in case the authors have an original
71 argument, adding some solid analysis about the relation of distance to open water bodies and
72 elevation in the discussion in order to exclude a possibility of redundancy;

73

74 **Response by authors**

75 The reviewer now pushes to remove the analysis on distance effects and demands original, sort
76 of climatological and/or physics based, arguments. Clearly, the used data set is limited and
77 effects of distances > 10 km only are minimal in this study. We disagree to the viewpoint that
78 advocates an in depth physics based analysis but we such analysis is outside the scope of this
79 study. Moreover, it would demand a specific targeted data set and targeted long term (> 5 years)
80 field survey. As described above, we revisited the analysis and added more comments on the
81 merits of the analysis, we also discusses findings and put findings in a broader perspective. We
82 note that still very little is known why SREs may perform poorly as related to specific real
83 world aspects. We note that researchers in the African continent in practice need to rely on
84 available, poorly designed, networks although well targeted and designed networks are needed.
85 As such to ignore findings from the available networks in Africa and the Zambezi Basin is not
86 considered appropriate but stresses that findings need to be described better. As such the
87 authors have extended descriptions on the analysis on distance to large scale water bodies.
88 To further stress the relevance of the analysis we note that our analysis were requested by an
89 earlier reviewer of the manuscript whose urged the need to assess effects of distance to the very
90 large lakes in the basin.

91

92 **Comment by reviewer**

93

94 2. I wonder whether the authors are familiar with the study by Xie et al. (2017, DOI:
95 10.1175/JHM-D-16-0168.1), which was published shortly before your submission. This seems
96 to be a very relevant study for this type of research. I understand that the timing was not the
97 best, but I suggest considering refining your discussion by using some insights from this global
98 scale analysis of the CMORPH datasets;

99

100 **Response by authors**

101 We thank the reviewer for this very relevant reference. We revisited the paper that in essence
102 introduces a global correction procedure to correct raw CMORPH estimates for land and ocean.
103 As such the correction procedure applies to very large spatial and temporal domains aiming to
104 correct for accumulated (bulk) rainfall. In essence a very relevant and urgently needed study
105 from a global perspective but the study only relies on PDF matching ignoring to address
106 specific influences that cause bias (either climatological or real time). We took notice of the
107 statement in the paper “*In applying the methodology to regions of very sparse gauge networks,*
108 *such as equatorial Africa, collocated gauge–CMORPH data pairs need to be collected over a*
109 *very large region of different weather regimes. The resulting PDF tables are therefore unable*
110 *to accurately represent the CMORPH bias structure over the target grid box, causing large*
111 *errors in the corrected CMORPH”* and indicates the problem for performing bias correction in
112 the Zambezi river basin with little ground truth but at the same time lots of demand on
113 developing and testing procedures to bias correct SREs for smaller domains so to make
114 applications meaningful to basin authorities and water resources managers. We like to refer to
115 Bhatti, H., Rientjes, T., Haile, A., Habib, E., Verhoef, W., Evaluation of Bias Correction
116 Method for Satellite-Based Rainfall Data, *Sensors* **16**(2016), p. 884 in which aspects of real
117 time refinements are addressed for the Gilgel Abbey catchment (1650 km²), Ethiopia. We also
118 refer to the studies we did in the Upper Blue Nile area in Ethiopia (171,529 km²) and extend
119 on those studies in this paper. We have chosen the Zambezi river basin since assessments in
120 the basin are very limited although there is urgent need to show if SREs are fit for applications.
121 We extend on our previous studies by testing for elevation effects and by testing if large scale
122 water bodies really affect SREs, that was suggested by an earlier reviewer.
123

124 **Comment by reviewer**

125 3. I am not surprised (not that I should be) that the STB was the best bias correction method.
126 This method forces the estimates to behave as observations. I was intrigued to know what the
127 implications of this result in the precipitation dynamics in this watershed are. In other words,
128 how would the authors explain the good efficiency of the linear method for the Zambezi River
129 basin?
130

131 **Response by authors**

132 We thank the reviewer for the comment. Linear models are somewhat brute force since indeed
133 the algorithm forces SRE’s to match rain gauge observations. By its simplicity there are quite
134 some constraints since there is not any specific parameterisation to correction in place. Actually
135 aspects of real world rainfall are ignored and thus rainfall dynamics are somewhat difficult to
136 represent. We added description on the role the 7-day sequential time window over which bias
137 factors are calculated. In the manuscript we address that more favourable results on bias
138 correction may result for remaining schemes when window length is extended, we actually
139 advocate further analysis.
140

141 **Comment by reviewer**

142

143 By the way, I suspect that Eq 1 is wrong (L287). Shouldn't the gauge rainfall (G) be divided
144 by the rainfall estimate (S)? And isn't the first S also spatiotemporal dependent?

145 **Response by authors**

146 We thank the reviewer for the comment and corrected our mistake. Equation 1 now reads:

147

$$148 \quad STB = S \frac{\sum_{t=d}^{t=d-l} G(i,t)}{\sum_{t=d}^{t=d-l} S(i,t)} \quad [1]$$

149

150

151 **Comment by reviewer**

152 4. One of the advantages of this study would be its application to other hydrological studies
153 since rainfall time series are scarce and difficult to obtain in this region. Bearing this in mind,
154 is the current manuscript providing enough information to be used in other studies? I am not
155 convinced about this. The current version of the manuscript does not provide a data statement
156 (required by HESS), and the authors could fill this gap in a very positive and supplemental
157 manner if they also provide useful information and datasets (e.g. add the best bias correction
158 factors to Appendix 1 and the raster of Fig. 2 as supplemental material/external dataset). I
159 believe it will cost you no substantial time, it will significantly improve the usability of your
160 research and be very appreciated by the community.

161

162 **Response by authors**

163 We thank the reviewer for the valuable suggestions. To improve the usability of our research,
164 the authors have provided a data statement as required by HESS. We have put supplementary
165 data to Appendix 1. We have also supplied the raster of Fig. 2 We have also provided other
166 raw and processed datasets such as the raingauge and uncorrected mean annual CMORPH
167 rainfall for the 60 raingauge stations. We have also provided as supplemental material/external
168 dataset, daily uncorrected CMORPH extracted rainfall for 54 raingauge stations from 1998-
169 2013 (excel spreadsheet). The maps provided are the mean annual rainfall (CMORPH &
170 Gauge), mean daily rainfall (CMORPH & gauge) and the percentage bias (Raster of Figure 2)
171 for the period 2013-present.

172 Daily rainfall values for the raingauges are not provided due to the restricting data policies by
173 the respective meteorological authorities.

174

175 Some observations and suggestions I found while reading the manuscript:

176 **Comment by reviewer**

177 L36: Here is a very appropriate place to name the correction schemes.

178

179 **Response by authors**

180 We thank the reviewer for the comment and now name the correction schemes on line 37 as
181 Spatio-temporal Bias (STB), Elevation Zone bias (EZ), Power transform (PT), Distribution
182 transformation (DT) and the Quantile mapping based on an empirical distribution (QME).

183

184 **Comment by reviewer**

185 L40: Why “whereas”? I did not understand the contrast.

186

187 **Response by authors**

188 We thank the reviewer for the comment.

189 The sentence now reads: ‘To evaluate effectiveness of the bias correction techniques, spatial
190 and temporal cross-validation was applied based on 8 stations and on the 1998-1999 CMORPH
191 time series, respectively’.

192

193 **Comment by reviewer**

194 L45: “Gauge estimates”. If the study considers the gauge data as the “real” rainfall, I suggest
195 to avoid use the term “estimate” to referring to it throughout the text.

196

197 **Response by authors**

198 The authors have avoided the use of the word “estimate” to refer to gauge rainfall. Instead
199 ‘raingauge rainfall’ is now used. However, we note that gauges measurements themselves
200 actually are estimates since gauges themselves also have error. The fact that measurements are
201 termed estimates is quite common nowadays in the work field.

202

203 **Comment by reviewer**

204 L47-51: If I understood it right, the bias is most overestimated for the very light rainfall (<2.5
205 mm/d), which is also the range that shows the best bias reduction, which in turn is most
206 effective during the wet season. Would be possible to rewrite these statements to improve its
207 concision?

208

209 **Response by authors**

210 This section is rewritten as:

211 Bias is most overestimated for the very light rainfall (<2.5 mm/d), which is also the range that
212 shows the best bias reduction, which in turn is most effective during the wet season. The above
213 is also shown through quantile-quantile (q-q) plots.

214

215 **Comment by reviewer**

216 L68-69: What water resources applications? I suggest the authors be more specific because I
217 cannot see that this is the focus of this study (as it is declared in the text).

218 **Response by authors**

219 We thank the reviewer for the comment and revised the sentence. It now reads:

220 In this study focus is on satellite rainfall estimates (SREs) to improve reliability in the spatio-
221 temporal rainfall representation.

222

223 **Comment by reviewer**

224 L83: This is the place where CMORPH should be written out (not in L110-111).

225

226 **Response by authors**

227 Recent studies on the National Oceanic and Atmospheric Administration (NOAA) Climate
228 Prediction Center-MORPHing (CMORPH) (Wehbe et al., 2017;Jiang et al., 2016;Liu et al.,
229 2015;Haile et al., 2015) reveal that accuracy of this CMORPH satellite rainfall product varies
230 across different regions, but causes are not directly identifiable.

231

232 **Comment by reviewer**

233 L105-107: Rewrite this sentence to connect it better to the rest of the paragraph.

234 **Response by authors**

235 Sentence rewritten as

236 The study by Tian (2010) in the United States noted that the Bayesian (likelihood) analysis
237 techniques are found to over-adjust both light and heavy satellite rainfall towards moderate
238 CMORPH rainfall.

239

240 **Comment by reviewer**

241 L121-122: Please, explain how SRE may be affected.

242 **Response by authors**

243 This sentence is revised to:

244 Besides elevation, there are indications that presence of Lake Tana ($\approx 3050 \text{ km}^2$, Ethiopia)
245 affects rainfall at short distances ($<10\text{km}$) (Haile et al., 2009; Rientjes et al., 2013a).

246

247 **Comment by reviewer**

248 L125: I do not think applications are limited. Do the authors mean past studies?

249

250 **Response by authors**

251 Sentence revised to: For less developed areas such as in the Zambezi Basin that is selected for
252 this study, past studies on SREs are limited.

253

254 **Comment by reviewer**

255 L134: I cannot see how these studies highlight the need to correct SREs, especially Cohen
256 Liechti et al. (2012: DOI: 10.5194/hess-16-489-2012), who reports that only 7% of the rainfall
257 in the Zambesi River basin contributes to runoff.

258

259 **Response by authors**

260 Sentence revised to:

261 ‘The poor performance of SREs in above studies urges for the need for bias correction’

262

263 **Comment by reviewer**

264 L149: I wonder what in science/hydrology has been fully investigated. Better rewrite this
265 science.

266

267 **Response by authors**

268 Sentence rewritten to ‘However studies on bias correction of CMORPH in the semi-arid
269 Zambezi Basin are limited’.

270

271 **Comment by reviewer**

272 L150: It is very obvious and general any improved data set or method in water resources is
273 important for IWRM. I suggest cutting through the jargon by removing this sentence.

274

275 **Response by authors**

276 Sentence removed

277

278 L157: Too many “applications”. Better rewrite it.

279 **Response by authors**

280 Sentence rewritten to:

281 ‘Analysis serve to improve reliability of SREs applications in water resource applications in
282 the Zambezi basin such as in drought analysis, flood prediction, weather forecasting and such
283 as for rainfall runoff modeling.’

284 We focus on rainfall runoff modelling since our next publication is on use of bias corrected
285 CMOPH for hydrological modelling.

286

287 **Comment by reviewer**

288 L178: What are the common types of precipitation in each of the regions in this river basin? Is
289 the orographic type significant? This information would probably support some results about
290 the elevation bias analysis.

291 **Response by authors**

292 The following paragraph has been added:

293 The basin lies in the tropics between 10 and 20 degrees South, encompassing humid, semi-arid
294 and arid regions dominated by seasonal rainfall patterns associated with the Inter-Tropical
295 Convergence Zone (ITCZ), a convective front oscillating along the equator (Cohen Liechti et
296 al., 2012). The movement of the ITCZ in Southern hemisphere results in the peak rainy season
297 that occurs during the summer (October to April) and the dry winter months (May-Sept) is a
298 result of the shifting back of ITCZ towards the equator (Schlosser and Strzepek, 2015). The
299 weather system in South Eastern parts such as Mozambique is dominated by Antarctic Polar
300 Fronts (APF) and Tropical Temperate Troughs (TTTs) occurrence which is positively related

301 to La Niña and Southern Hemisphere planetary waves, while El Niño-Southern Oscillation
302 (ENSO) appears to play a significant role in causing dry conditions in the basin (Beilfuss,
303 2012).

304

305 **Comment by reviewer**

306 L197: What is the original source of this data? Does this data repository belongs to this software
307 or to the NOAA?

308

309 **Response by authors**

310 Sentence revised to:

311 ‘For this study, time series of CMORPH rainfall images (1998-2013) at 8 km × 8 km, 30-
312 minute resolution were selected and downloaded from the NOAA repository
313 (ftp://ftp.cpc.ncep.noaa.gov/prep/CMORPH_V1.0/CRT/8km.30m/). Images are downloaded
314 by means of the GeoNETCAST ISOD toolbox of ILWIS GIS software
315 (<http://52north.org/downloads/>). Half hourly estimates were aggregated to daily totals to match
316 the observation interval of gauge based daily rainfall’.

317

318 **Comment by reviewer**

319 L206: Since the criteria to filter the stations is not shown, I suggest to skip this vague statement
320 and go straight to a statement that defines the number of stations used.

321

322 **Response by authors**

323 Following the suggestion of the reviewer, we have skipped criteria to filter the stations.
324 Paragraph now reads:

325 ... Time series of daily rainfall from 60 stations were obtained from meteorological departments
326 in Botswana, Malawi, Mozambique, Zambia and Zimbabwe for stations that cover the study
327 area. All the stations are standard type raingauges with a measuring cylinder whose units of
328 measurement is millimetres (mm).

329 Some stations are affected by data gaps but the available time series are of sufficiently long
330 duration (see Appendix 1)) to serve the objectives of this study....

331

332 **Comment by reviewer**

333 L208: Here is a good place to mention the Appendix 1 (you do not need to remove it from
334 L240).

335 **Response by authors**

336 Appendix 1 mentioned in line 238.

337

338 **Comment by reviewer**

339 L215: I find it odd that nothing about the assumption that the rainfall within the 8 x 8 km pixels
340 is taken as homogenous. This could be used to discuss, later on, some bias found in this study.

341 **Response by authors**

342 The added discussion section is now mentioning the issue of spatial resolution of the rainfall
343 input.

344

345 **Comment by reviewer**

346 L246: How this 700 km² threshold was defined? It needs to be explained in the manuscript.
347 Large lakes are often considered as water bodies with surface areas over 50 km².

348

349 **Response by authors**

350 The threshold is defined based on knowledge of the water bodies in the study area. A
351 preliminary analysis on 300 water bodies in the study area revealed that only surface areas >
352 700 km² induce significant effect on rainfall patterns.

353

354 **Comment by reviewer**

355

356 As other reviewers pointed out, the figures need some major work:

357 **Comment by reviewer**

358 Figure 1: a) the map is polluted with unnecessary information: African country names (in the
359 continental map – then this map can be reduced to give some more space to the main map),
360 rainfall gauge station names; b) the elevation palette is not helping its visualization (suggestion:
361 leave it as monochromatic); c) Please improve the river streamline; d) since the results are
362 sectioned in lower, middle and upper Zambezi, it would be very useful show these regions in
363 this map.

364 **Response by authors**

365 Figure 1 improved following recommendations by reviewer.

366

367 **Comment by reviewer**

368 Figure 2: what bias is shown on this map? The manuscript presents many bias schemes and on
369 this map it is only written as “bias”;

370 **Response by authors**

371 Figure 2 improved. Bias referred to here is for uncorrected CMORPH bias and this is corrected
372 on the map.

373 Figure 2 caption now reads:

374 Figure 2: The spatial variation of bias (%) for gauge vs uncorrected CMORPH daily rainfall
375 (1998-2013) for the Zambezi Basin. The gauge based isohyets for Mean Annual Precipitation
376 (MAP) are shown in blue.

377

378 **Comment by reviewer**

379 Figures 3 and 10: a) the axes of these images are not at the same scale; b) the line colours,
380 patterns and thickness do not help the visualization of results. Please keep in mind that this is
381 a graphic that is summarizing many results, therefore it should be very well made.

382 **Response by authors**

383 Figure 3 and improved and now more visible. The axes of these images are now the same scale.
384 The line colours, patterns and thickness have been modified to help the visualization of results.

385

386 **Comment by reviewer**

387 Figures 5 and 9: Please, do not use 3D-like effects (or similar) in this type of graphics.

388 **Response by authors**

389 3D effects removed in all graphs.

390

391 **Comment by reviewer**

392 Figure 4: It is strange that according to the gauge data in this graphic the mean annual
393 precipitation to all Zambezi regions is lower than 1000 mm/year. It contradicts the information
394 in L178.

395

396 **Response by authors**

397 Coherence is made to the information in the graph and text concerning mean annual
398 precipitation. However the graph shows the minimum, maximum precipitation and estimated

399 ratio not mean annual precipitation. The range of values of max precipitation for both corrected
400 and uncorrected CMORPH is 227-142.6 mm/day.

401

402 **Comment by reviewer**

403 For all figures (except Fig 4 and 9): improve resolution, captions and sharpness of each element
404 in the figures.

405

406 **Response by authors**

407 All Figures improved following recommendations by reviewer.

408 **Comment by reviewer**

409 In the text: please avoid to give any role to the figures but visualization (e.g. do not use the
410 term “Figure reveals” L557).

411

412

413 **Response by authors**

414 This is corrected in the manuscript.

415

416 **Comment by reviewer**

417 I am not convinced that the results and discussion as one section was a good choice for this
418 manuscript. As it was mentioned, the discussion is often forgotten and this section remains
419 with a structure that is primarily made to present results (e.g. “Standard statistics”,
420 “Significance testing”, “Taylor diagrams”, “q-q plots” subsections).

421 **Response by authors**

422 Results separated from discussion.

423 **Comment by reviewer**

424 This section also has a considerable amount of methodological information, which should have
425 remained in the methodology.

426

427 **Response by authors**

428 Authors have removed all methodological information from results section.

429 **Comment by reviewer**

430 I cannot see the relevance of the conclusion “3” in this section (surely it is important in the
431 discussion, but not in the conclusions). This section is somehow addressing the three main
432 objectives of the study (L152-159), but it needs to be more concise.

433

434 **Response by authors**

435 Section now more conscious. A new conclusion ‘3’ has been inserted.

436

437 **Comment by reviewer**

438 Last but not least: the manuscript still shows some typos, doubtful word choices and vague
439 statements. It would be very positive if the authors read the text carefully and feel free to do
440 any type of improvements in the text. It will surely be positive for the review process as well
441 as for the reading experience of this manuscript.

442

443 **Response by authors**

444 Authors have meticulously addressed the typos and vague statements in the manuscript.

445

446

447

448 **Performance of bias correction schemes for CMORPH**
449 **rainfall estimates in the Zambezi River Basin**

478 Abstract

479 Satellite Rainfall Estimates (SRE) are prone to bias as they are indirect derivatives of the
480 visible, infrared, and/or microwave cloud properties, hence SREs need correction. We evaluate
481 the influence of elevation and distance from large scale open water bodies on bias for Climate
482 Prediction Center-MORPHing (CMORPH) rainfall estimates in the Zambezi Basin. The
483 effectiveness of five linear/non-linear and time-space variant/invariant bias correction schemes
484 was evaluated for daily rainfall estimates and climatic seasonality. Schemes used are: Spatio-
485 temporal Bias (STB), Elevation Zzone bias (EZ), Power transform (PT), Distribution
486 transformation (DT) and the Quantile mapping based on an empirical distribution (QME). -We
487 used daily time series (~~1999~~1998-2013) from ~~52-60~~ gauge stations and ~~for~~ CMORPH SREs for
488 the Zambezi Basin. To evaluate effectiveness of the bias correction techniques, spatial and
489 temporal cross-validation was applied based on 8 stations and on ~~whereas and temporal cross-~~
490 ~~validation was based on~~ the 1998-1999 CMORPH time series, respectively. A For correction,
491 ~~the Spatio-temporal Bias (STB) and Elevation Zone bias (EZ) schemes~~ proved to be more
492 effective in removing bias. STB improved the correlation coefficient and Nash Sutcliffe
493 efficiency by 50 % and 53 % respectively and reduced the root mean squared difference and
494 relative bias by 25 % and 33 % respectively. Paired t-tests showed that there is no significant
495 difference ($p < 0.05$) in the daily means of CMORPH against gauge ~~estimates-rainfall~~ after bias
496 correction. ~~whereas~~ ANOVA post-hoc tests revealed ed that the STB and EZ bias correction
497 schemes are preferable. Bias is most overestimated is highest for the very light rainfall (<2.5
498 mm/d), which is also the range that shows the for which most effective best bias reduction is
499 shown, in particular for the, which in turn is most effective during the wet season. Similar
500 findings The above is also are shown through quantile-quantile (q-q) plots. The spatial cross-
501 validation approach revealed that the majority of the bias correction schemes removed bias by
502 ≥ 28 %. The temporal cross-validation approach showed ~~in some instances the~~ effectiveness of
503 the bias correction schemes. Taylor diagrams show that station elevation ~~and distance from~~
504 ~~large scale open water bodies~~ has an influence on CMORPH performance. Effects of
505 distance- >10m from large scale open water bodies are minimum whereas the effect at shorter
506 distances are indicat~~ed~~ but not conclusive by lack of raingauges. Findings of this study show
507 the importance of applying bias correction to SREs, satellite rainfall estimates ~~before for~~
508 ~~application in hydrological analyses.~~

513

514 1. Introduction

515

516 Correction schemes for rainfall estimates are developed for climate models (Maraun,
517 2016;Grillakis et al., 2017;Switanek et al., 2017), for radar approaches (Cecinati et al.,
518 2017;Yoo et al., 2014) and for satellite based, multi-sensor approaches (Najmaddin et al.,
519 2017;Valdés-Pineda et al., 2016). In this study focus is on satellite rainfall estimates (SREs) to
520 improve reliability in [water resource applications](#) [spatio-temporal rainfall representation](#).

521

522 Studies in satellite based rainfall estimation show that estimates are prone to systematic and
523 random errors (Gebregiorgis et al., 2012;Habib et al., 2014;Shrestha, 2011;Tefagiorgis et al.,
524 2011;Vernimmen et al., 2012;Woody et al., 2014). Errors result primarily from the indirect
525 estimation of rainfall from visible (VIS), infrared (IR), and/or microwave (MW) based satellite
526 remote sensing of cloud properties (Pereira Filho et al., 2010; Romano et al., 2017). Systematic
527 errors in SREs commonly are referred to as bias, which is a measure that indicates the
528 accumulated difference between rain gauge observations and SREs. Bias in SREs is expressed
529 for rainfall depth (Habib et al., 2012b), rain rate (Haile et al., 2013) and frequency at which
530 rain rates occur (Khan et al., 2014). Bias may be negative or positive where negative bias
531 indicates underestimation whereas positive bias indicates overestimation (Liu, 2015; Moazami
532 et al., 2013).

533

534 Recent studies on- [the National Oceanic and Atmospheric Administration \(NOAA\) Climate](#)
535 [Prediction Center-MORPHing \(CMORPH\)](#) [CMORPH](#) (Wehbe et al., 2017;Jiang et al., 2016;
536 Liu et al., 2015; Haile et al., 2015) reveal that accuracy of [thisCMORPH](#) satellite rainfall
537 product varies across different regions, but causes are not directly indentifiable. As such
538 correction schemes serve to reduce systematic errors and to improve applicability of SREs.
539 Correction schemes rely on assumptions that adjust errors in space and/or time (Habib et al.,
540 2014). Some correction schemes consider correction only for spatial distributed patterns in
541 bias, commonly known as space variant/invariant. Approaches that correct for spatially
542 averaged bias have roots in radar rainfall estimation (Seo et al., 1999) but are unsuitable for
543 large scale basins ($> 5,000 \text{ km}^2$) where rainfall may substantially vary in space (Habib et al.,
544 2014). Studies by Tefagiorgis et al. (2011) in Oklahoma (USA) and Müller and Thompson
545 (2013) in Nepal concluded that space variant correction schemes are more effective in reducing

546 CMORPH and TRMM bias than space invariant correction schemes. In a study conducted in
547 the Upper Blue Nile basin in Ethiopia, Bhatti et al. (2016) show that CMORPH bias correction
548 is most effective when bias factors are calculated for~~correction is for~~ a 7 day sequential
549 windows.

550
551 Bias correction schemes based on regression techniques have reported distortion of frequency
552 of rainfall rates (Ines and Hansen, 2006; Marcos et al., 2018). Multiplicative shift procedures
553 tend to adjust SRE rainfall rates, but Ines and Hansen (2006) reported that they do not correct
554 systematic errors in rainfall frequency of climate models. Non-multiplicative bias correction
555 schemes preserve the timing of rainfall within a season (Fang et al., 2015; Hempel et al., 2013).
556 Studies that have applied non-linear bias correction schemes such as Power Function report
557 correction of extreme values (depth, rate and frequency) thus mitigating the underestimation
558 and overestimation of CMORPH rainfall (Vernimmen et al., 2012). The study by Tian (2010)
559 in the United States noted that the Bayesian (likelihood) analysis techniques are found to over-
560 adjust both light and heavy ~~satellite rainfall towards moderate~~ CMORPH rainfall.

561
562 Bias often exhibits a topographic and latitudinal dependency as, for instance, shown for ~~the~~
563 ~~National Oceanic and Atmospheric Administration (NOAA) Climate Prediction Center-~~
564 ~~MORPHing~~ CMORPH product in the Nile Basin (Bitew et al., 2011; Habib et al., 2012a; Haile
565 et al., 2013). For Southern Africa, Thorne et al. (2001), Dinku et al. (2008) and Meyer et al.
566 (2017) show that bias in rainfall rate and frequency can be related to location, topography, local
567 climate and season. First studies in the Zambezi Basin (Southern Africa) on SREs show
568 evidence that necessitates correction of SREs. For example, Cohen Liechti (2012) show bias
569 in CMORPH SREs for daily rainfall and for accumulated rainfall at monthly scale. Matos et
570 al. (2013), Thiemiig et al. (2012) and Toté et al. (2015) show that bias in rainfall depth at time
571 intervals ranging from daily to monthly varies across geographical domains in the Zambezi
572 Basin and may be as large as $\pm 50\%$. Besides elevation,~~topographic effects, there are~~
573 indications that rainfall is affected by presence of -Lake Tana ($\approx 3050 \text{ km}^2$, Ethiopia) large scale
574 open water bodies that which affects rainfall at short distances ($<10\text{km}$) (Haile et al., 2009; ;
575 Rientjes et al., 2013a). influences surface or atmospheric properties as shown in (Haile et al.,
576 2009; Rientjes et al., 2013a) for relatively short distances ($<50 \text{ km}$) to Lake Tana, Ethiopia.
577 As such, As such SREs may be affected as well./ as suggested in.

578 ~~Besides topographic effects, rainfall is affected by presence of large scale open water bodies~~
579 ~~which influences surface or atmospheric properties . As such, SREs may be affected as well as~~
580 ~~suggested in (Rientjes et al., 2013b).~~

581

582 For less developed areas such as in the Zambezi Basin that is selected for this study,
583 ~~applications of past studies on~~ SREs are limited. This is despite the strategic importance of the
584 basin in providing water to over 30 million people (World Bank, 2010a). An exception is the
585 study by Beyer et al. (2014) on correction of the TRMM-3B42 product for agricultural purposes
586 in the Upper Zambezi Basin. Studies (Cohen Liechti et al., 2012; Meier et al., 2011) -on use of
587 SREs in the Zambezi River Basin mainly focused on accuracy assessment of the SREs using
588 standard statistical indicators with little or no effort to perform bias correction despite the
589 evidence of errors in these products. The use of uncorrected ~~satellite rainfall~~SREs is reported
590 for hydrological modelling in the Nile Basin (Bitew and Gebremichael, 2011) and Zambezi
591 Basin (Cohen Liechti et al., 2012), respectively, and for drought monitoring in Mozambique
592 (Toté et al., 2015). The ~~degree of poor performance of SREs performance in~~ above studies
593 ~~highlight pushes urges for reliable~~the need to correct SREs for bias correction to result in more
594 accurate rainfall representation. The selection of CMORPH satellite rainfall for this study is
595 based on successful applications of bias corrected CMORPH estimates in African basins for
596 hydrological modelling (Habib et al., 2014) and flood predictions in West Africa (Thiemig et
597 al., 2013). In first publications on CMORPH, Joyce et al. (2004) describe CMORPH as a
598 gridded precipitation product that estimates rainfall with information derived from IR data and
599 MW data. CMORPH combines the retrieval accuracy of passive MW estimates with IR
600 measurements which are available at high temporal resolution but with low accuracy. The
601 important distinction between CMORPH and other merging methods is that the IR data are not
602 used for rainfall estimation but used only to propagate rainfall features that have been derived
603 from microwave data. The flexible ‘morphing’ technique is applied to modify the shape and
604 rate of rainfall patterns. CMORPH is operational since 2002 for which data is available at the
605 CPC of the National Centers for Environmental Prediction (NCEP) (after
606 <http://www.ncep.noaa.gov/>). Recent publications on CMORPH in African basins exist (Wehbe
607 et al., 2017;Koutsouris et al., 2016;Jiang et al., 2016;Haile et al., 2015). However, studies on
608 bias correction of CMORPH data applicability after bias correction in the semi-arid Zambezi
609 Basin ~~has not been fully investigated~~are limited. ~~Therefore, evaluating and finding the~~

610 ~~appropriate bias correction method for the data is necessary for water resources management~~
611 ~~in the basin.~~

612

613 In this study we use daily CMORPH and rain gauge data for Upper, Middle, and Lower
614 Zambezi basins to (1) evaluate if performance of CMORPH rainfall is affected by elevation
615 and distance from large scale open water bodies (2) evaluate the effectiveness of linear/non-
616 linear and time-space variant/invariant bias correction schemes and (3) assess the performance
617 of bias correction schemes to represent different rainfall rates and climate seasonality. Analysis
618 serve to improve reliability of SREs applications in water resource applications in the Zambezi
619 basin ~~such as in drought analysis, flood prediction, weather forecasting and such as for rainfall-~~
620 runoff modeling

621

622 2. Study area

623 The Zambezi River is the fourth-longest river (~2,574 km) in Africa with basin area of
624 ~1,390,000 km² (~4 % of the African continent). The river drains into the Indian Ocean and
625 has mean annual discharge of 4,134 m³/s (World Bank, 2010a). The river has its source in
626 Zambia with basin boundaries in Angola, Namibia Botswana, Zambia, Zimbabwe and
627 Mozambique (Fig. 1). The basin is characterized by considerable differences in elevation and
628 topography, distinct climatic seasons and presence of large scale open water bodies and, as
629 such, makes the basin well suited for this study. The basin is divided into three subbasins i.e.,
630 the Lower Zambezi comprising the Tete, Lake Malawi/Shire, and Zambezi Delta basins, the
631 Middle Zambezi comprising the Kariba, Mupata, Kafue, and Luangwa basins, and the Upper
632 Zambezi comprising the Kabompo, Lungwebungo, Luanginga, Barotse, and Cuando/Chobe
633 basins (Beilfuss, 2012).

634

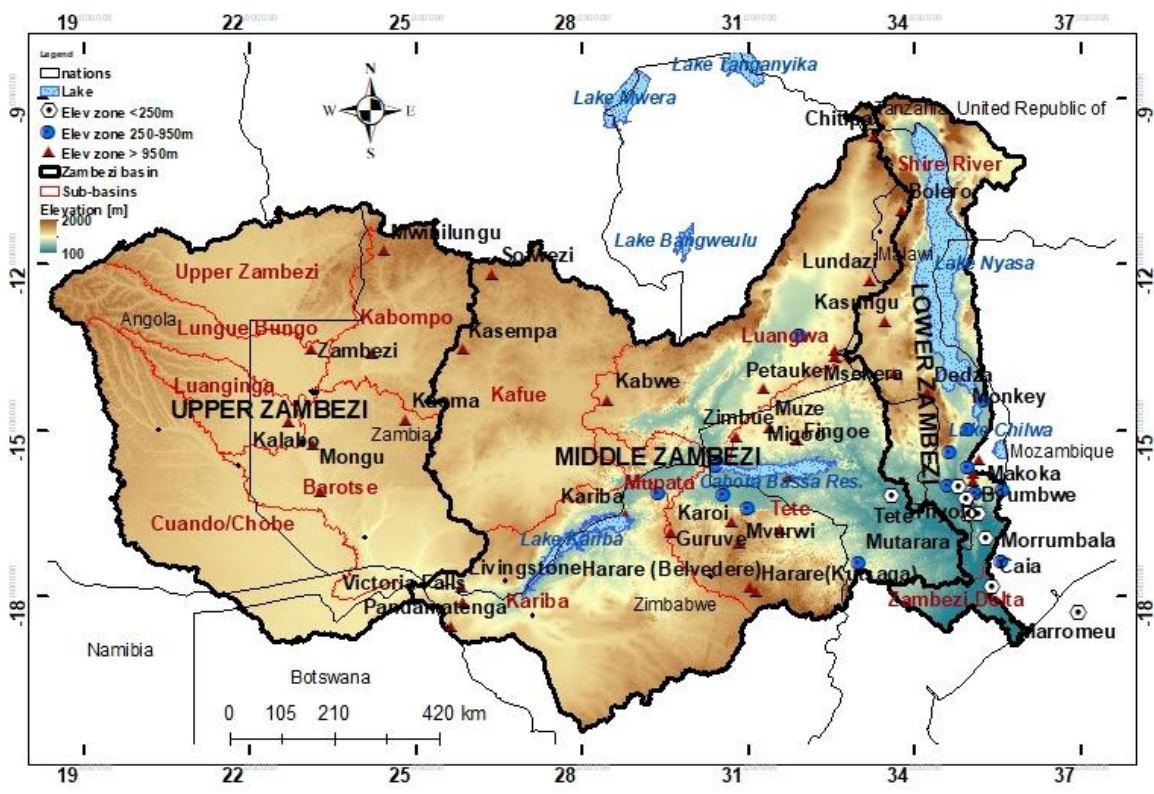

635 The elevation of the Zambezi basin ranges from < 200 m (for some parts of Mozambique) to
636 >1500 m above sea level (for some parts of Zambia). Large scale open water bodies in and
637 around the basin are Kariba, Cabora Bassa, Bangweulu, Chilwa and Nyasa. The Indian Ocean
638 ~~is lies~~ to the east of Mozambique. Typical landcover types are woodland, grassland, water
639 surfaces and cropland (Beilfuss et al., 2000). The basin lies within the tropics between 10 and
640 20 degrees S South, encompassing humid, semi-arid and arid regions dominated by seasonal
641 rainfall patterns associated with the Inter-Tropical Convergence Zone (ITCZ), a convective
642 front oscillating along the equator (Cohen Liechti et al., 2012). The movement of the ITCZ in

643 Southern hemisphere results in the peak rainy season that occurs during the summer (October
 644 to April) and the dry winter months (May-Sept) is a result of the shifting back of ITCZ towards
 645 the equator (Schlosser and Strzepek, 2015)-. The weather system in South Eastern parts such
 646 as Mozambique is dominated by Antarctic Polar Fronts (APF) and Tropical Temperate Troughs
 647 (TTTs) occurrence which is positively related to La Niña and Southern Hemisphere planetary
 648 waves, while El Niño-Southern Oscillation (ENSO) appears to play a significant role in causing
 649 dry conditions in the basin (Beilfuss, 2012).

650

651 The basin is characterized by high annual rainfall (>1,400 mm/yr) in the northern and north-
 652 eastern areas and by but low annual rainfall (<500 mm/yr) in the southern and western parts
 653 (World Bank, 2010b). Due to this rainfall distribution, northern tributaries in the Upper
 654 Zambezi subbasin contribute 60 % of the mean annual discharge (Tumbare, 2000). The river
 655 and its tributaries are subject to seasonal floods and droughts that have devastating effects on
 656 the people and economies of the region, especially the poorest members of the population
 657 (Tumbare, 2005). It is not uncommon to experience both floods and droughts within the same
 658 hydrological year.

659

660

661 Figure 1: Zambezi River Basin from Africa with sub basins, major lakes, ~~rivers~~, elevation, and locations and names of the 60
662 rain gauging stations (in each respective elevation zone) used in this study. ~~The Euclidian distance (km) from large scale open~~
663 ~~water bodies is also shown.~~

665 3. Materials and Methodology

666 3.1. Rainfall data

667 3.1.1. CMORPH

669 For this study, time series of CMORPH rainfall images (1998-2013) at $8\text{ km} \times 8\text{ km}$, 30-minute
670 resolution were selected and downloaded from the NOAA repository
671 (ftp://ftp.cpc.ncep.noaa.gov/prep/CMORPH_V1.0/CRT/8km.30m/). Images are downloaded
672 by means of the GeoNETCAST ISOD toolbox of ILWIS GIS software
673 (<http://52north.org/downloads/>). Half hourly estimates were aggregated to daily totals to match
674 the observation interval of gauge based daily rainfall.

675 3.1.2. Rain gauge network

677 Time series of daily rainfall from ~~66-60~~ stations were obtained from meteorological
678 departments in Botswana, Malawi, Mozambique, Zambia and Zimbabwe for stations that cover
679 the study area. All the stations are standard type raingauges with a measuring cylinder whose
680 units of measurement is millimetres (mm).

682 ~~After screening, 6 stations with suspicious time series were removed to remain with 60 stations.~~
683 Some stations are affected by data gaps but the available time series are of sufficiently long
684 duration (see Appendix 1) to serve the objectives of this study. Stations are irregularly
685 distributed across the vast basin and are located at elevation between 3 m to 1575 m (Figure
686 1). The minimum, maximum and average distance between the rain-gauges is 3.5 km (Zumbo
687 in Mozambique-Kanyemba in Zimbabwe), 1570 km (Mwinilunga in Zambia-Marromeu in
688 Mozambique) and 565 km respectively. ~~This variation of distances provides a good spatial~~
689 ~~base for analysis in ths study. Stations are located between an elevation range of 3 m to 1600~~
690 ~~masl.~~ Distances to large scale open water bodies range between 5 km and 615 km. This allows
691 us to evaluate if elevation and distance to large scale open water bodies affect CMORPH
692 performance.

693 3.1.3. Comparison of CMORPH and ~~rain-gauge~~ estimates rainfall

695 In this study, we compare ~~rain-gauge estimates-rainfall-~~ at point scale to CMORPH satellite
696 derived rainfall estimates at pixel scale (point-to-pixel). Comparison is at a daily time interval
697 covering the period 1998-2013, following (Cohen Liechti et al. (2012), Dinku et al. (2008;
698), Haile et al. (2014), Hughes (2006), Tsidu (2012) and Worqlul et al. (2014) who
699 report on point-to-pixel comparisons in African basins. We apply point-to-pixel comparison to
700 rule out any aspect of interpolation error as a consequence of the low density network with
701 unevenly distributed stations. We refer to (Heidinger et al. (2012), Li and Heap (2011),
702 Tobin and Bennett (2010) and Yin et al. (2008) who report that interpolation introduces
703 unreliability and uncertainty to pixel based rainfall estimates. Also, Worqlul et al. (2014)
704 describe that for pixel-to-pixel comparison, there is demand for a well distributed rain-gauge
705 network that would not hamper accurate interpolation.

706

707 3.2. Elevation and distance from large scale open water bodies

708 ~~Studies~~ Habib et al. (2012a), Haile et al. (2009) and Rientjes et al. (2013a) for the Nile Basin
709 reveal that elevation affect performance of SREs. Findings in the latter two studies signal that
710 performance possibly also may be affected by presence of Lake Tana. To assess both such
711 influences, we classified the Zambezi Basin into 3 elevation zones for which the hierarchical
712 cluster ‘within-groups linkage’ method in the Statistical Product and Service Solutions (SPSS)
713 software was used (Table 1). Based on Euclidian distance to large-scale open water bodies, 4
714 arbitrary distance zones are defined to group stations (Table 1). A detailed description on the
715 individual stations, their elevation and distance to large-scale open water bodies is provided in
716 Appendix 1. The Advanced Spaceborne Thermal Emission and Reflection Radiometer
717 (ASTER) based DEM of 30 m resolution obtained from
718 <http://gdem.ersdac.jspacesystems.or.jp/>, is used to represent elevation across the Zambezi
719 Basin. The Euclidian distance of each rain-gauge location to large-scale open water bodies is
720 defined in a GIS environment through the distance calculation algorithm. Large-scale open
721 water bodies are defined as perennial open water bodies with surface area > 700 km².

722

723 Table 1: Elevation and distance from large scale open water bodies

Zone ID	Elevation (m)	No. of stations	Mean elevation of stations (m)
Zone 1	< 250	8	90
Zone 2	250-950	21	510
Zone 3	> 950	31	1140

Zone ID	Distance (km)	No. of stations	Mean distance to large-scale open water bodies (km)
Zone 1	< 10 km	4	5
Zone 2	10 - 50	10	35
Zone 3	50 - 100	18	80
Zone 4	> 100	28	275

724

725 3.3. Bias correction schemes

726 Bias correction schemes evaluated in this study are the Spatio-temporal bias (STB), Elevation
727 zone bias (EZ), Power transform (PT), Distribution transformation (DT), and the Quantile
728 mapping based on an empirical distribution (QME). this by -our aim to correct for bias while
729 daily rainfall variability is preserved. The five schemes are chosen based on merits documented
730 in literature (Bhatti et al., 2016; Habib et al., 2014; Teutschbein and Seibert, 2013; Themeßl et
731 al., 2012; Vernimmen et al., 2012). ~~-, since we aim to correct while daily rainfall variability is~~
732 ~~preserved.~~ We note that findings on the performance of selected bias correction schemes in
733 literature do not allow for generalization but findings only apply to the respective study
734 domains (Wehbe et al., 2017; Jiang et al., 2016; Liu et al., 2015; Haile et al., 2015).

735

736 In the procedure to define a time window for bias correction we follow Habib et al. (2014) and
737 Bhatti et al. (2016) who in the Lake Tana Basin (Ethiopia) carried out a sensitivity analysis on
738 moving time windows and on sequential time windows. Window lengths of 3 and 31 days are
739 tested. Findings indicated that a 7-day sequential time window for bias factors is most
740 appropriate but only when a minimum of five rainy days were recorded within the 7-day
741 window with a minimum rainfall accumulation depth of 5 mm, otherwise no bias is estimated
742 (i.e. a value of 1 applies as bias correction factor). Preliminary tests in this study on 5 and 7-
743 day moving and sequential windows on 20 individual stations distributed over the three
744 elevation zones indicates that the 7-day sequential approach is well applicable in the Zambezi
745 Basin. As such, ~~the approach was selected.~~

746

747 The bias correction factors are calculated using only rain days (rainfall ≥ 1 mm). Otherwise in
748 cases where both the gauge and satellite have zero values (RG=0 and CMORPH =0), correction
749 is not applied and the SRE value remains 0 mm/day.

750

751 Following Bhatti et al. (2016), we spatially interpolated the bias correction factors of the rain
752 gauges so that ~~factors are subsequently applied to all~~ SREs at all pixels can be corrected. For

753 interpolation, the -Universal Kriging was applied. Thus to systematically correct all CMORPH
754 estimates, station based bias factors for each time window are spatially interpolated to arrive
755 at spatial coverage across the study area and to allow for comparison with other approaches.

756

757 3.3.1. Spatio-temporal bias correction (STB)

758 This linear bias correction scheme has its origin in the correction of radar based precipitation
759 estimates (Tefagiorgis et al., 2011) and downscaled precipitation products from climate
760 models. -The CMORPH daily rainfall estimates (S) are multiplied by the bias correction factor
761 for the respective sequential time window for individual stations resulting in corrected
762 CMORPH estimates (STB) in a temporally and spatially coherent manner (Equation [1]).

$$763 \quad STB = S \frac{\sum_{t=d}^{t=d-l} G(i,t)}{\sum_{t=d}^{t=d-l} S(i,t)} \quad [1]$$

764 Where:

765 G = gauged rainfall-estimate-(mm/day)

766 i = gauge number

767 d = day number

768 t = julian day number

769 l = length of a time window for bias correction

770

771 The advantages of this bias correction scheme is that it is straightforward and easy to implement
772 due to its simplicity and modest data requirements. However, just like any multiplicative shift
773 procedures of bias correction, STB ~~-does not has challenges in~~ correct- intensities ~~(I think this~~
774 is not true?) ~~-and~~ systematic errors in rainfall frequency particularly the wet-day frequencies
775 (Lenderink et al., 2007; Teutschbein and Seibert, 2013).

776

777 3.3.2. Elevation zone bias correction (EZ)

778 This bias scheme is proposed in this study and aims at correcting satellite rainfall for elevation
779 influences. This method groups rain-gauge stations into 3 elevation zones based on station
780 elevation. The grouping in this study is based on the hierarchical clustering technique, expert
781 knowledge about the study area but also guided by relevant past studies in the basin (e.g. World
782 Bank, 2010b;Beilfuss, 2012). Each zone has the same bias correction factor but differs across
783 the three zones. In the time domain bias factors vary following the 7-day sequential window

784 approach. The corrected CMORPH estimates (EZ) at daily time interval are obtained by
 785 multiplying the uncorrected CMORPH daily rainfall estimates (S) by the daily bias correction
 786 factor of each elevation zone.

787

$$788 \quad EZ = S \frac{\sum_{t=d}^{t=d-l} \sum_{i=1}^{i=n} G(i, t)}{\sum_{t=d}^{t=d-l} \sum_{i=1}^{i=n} S(i, t)} \quad [2]$$

789

790 The merits of this bias correction scheme is that the effects of elevation on rainfall depth are
 791 accounted for. SREs often have difficulties in capturing rainfall events due to orographic
 792 effects and thus require elevation based correction.

793

794 3.3.3. Power transform (PT)

795 The non-linear PT bias correction scheme has its origin in studies of climate change impact
 796 (Lafon et al., 2013). Vernimmen et al. (2012) show that the scheme could be applied to correct
 797 satellite rainfall estimates for use in hydrological modelling and drought monitoring. The PT
 798 method uses an exponential form to adjust the standard deviation of rainfall series. The daily
 799 bias corrected CMORPH rainfall (PT) for a pixel that overlays a station is obtained using
 800 equation:

801

$$802 \quad PT = aG(i, t)^b \quad [3]$$

803 Where:

804 G = rain-gauged rainfall-estimate (mm/day)

805 a = prefactor such that the mean of the transformed CMORPH values is equal to the mean
 806 of rain gauge estimates rainfall

807 b = factor calculated such that for each rain gauge the coefficient of variation (CV) of
 808 CMORPH matches the gauge based counter parts

809 i = gauge number

810 t = day number

811

812 Optimized values for a and b are obtained through the generalized reduced gradient algorithm
 813 (Fylstra et al., 1998). Values for a and b vary for the 7-day time sequential window since
 814 correction is at daily time base. In the case of utilizing the PT method in a certain area (or for a

815 certain period), the bias correction factor is spatially interpolated to result in comparable
 816 estimates with other bias correction schemes. The advantage of the bias scheme is that it adjusts
 817 extreme precipitation values in CMORPH estimates (Vernimmen et al., 2012). PT has reported
 818 limitations in correcting wet-day frequencies and intensities (Leander et al., 2008; Teutschbein
 819 and Seibert, 2013).

820

821 3.3.4. Distribution transformation (DT)

822 DT is an additive bias correction approach which has its origin in statistical downscaling of
 823 climate model data (Bouwer et al., 2004). The method transforms a statistical distribution
 824 function of daily CMORPH rainfall estimates to match the distribution by gauged rainfall. The
 825 procedure to match the CMORPH distribution function to gauge rainfall based counter parts is
 826 described in equations [4-8]. The principle to matching is that the difference in the mean value
 827 and differences in the variance are corrected for, in the 7-day sequential window. First, the bias
 828 correction factor for the mean (DT_u) is determined by equation [4]:

829

$$830 \quad DT_u = \frac{G_u}{S_u} \quad [4]$$

831 G_u and S_u are mean values of 7-day gauge and CMORPH rainfall estimates.

832

833 Secondly, the correction factor for the variance (DT_τ) is determined by the quotient of the 7-
 834 day standard deviations, G_τ and S_τ , for gauge and CMORPH respectively.

835

$$836 \quad DT_\tau = \frac{G_\tau}{S_\tau} \quad [5]$$

837

838 Once the correction factors which vary within a 7-day time sequential window are established,
 839 they are then applied to correct all daily CMORPH estimates (S) through equation [6] to obtain
 840 corrected CMORPH rainfall estimate (DT). The parameters DT_u and DT_τ are developed within
 841 a 7-day sequential window but correction is ~~then~~ at daily time intervals.

842

$$843 \quad DT = (S(i, t) - S_u)DT_\tau + DT_u * S_\tau \quad [6]$$

844 Uncorrected CMORPH daily values are returned if [6] results in negative values. The merit of
 845 this bias correction scheme is that it corrects wet-day frequencies and intensities. The
 846 disadvantage of this bias correction scheme is that adding the gauge based mean deviation to

847 the satellite data destroys the physical consistency of the data. In addition, the method might
848 result in the generation of too few rain days in the wet season, and sometimes the mean of daily
849 intensities might be unrealistically corrected (Johnson and Sharma, 2011; Teutschbein and
850 Seibert, 2013).

851

852 3.3.5. Quantile mapping based on an empirical distribution (QME)

853 This is a quantile based empirical-statistical error correction method with its origin in empirical
854 transformation and bias correction of regional climate model-simulated precipitation (Themeßl
855 et al., 2012). The method corrects CMORPH precipitation based on empirical cumulative
856 distribution functions (*ecdfs*) which are established for each 7-day time window and for each
857 station. The bias corrected rainfall (*QME*) using quantile mapping are expressed in terms of
858 the empirical cumulative distribution function (*ecdf*) and its inverse ($ecdf^{-1}$). Parameters apply
859 to a 7-day sequential window but correction is then at daily time interval with bias spatially
860 averaged for the entire domain to allow for comparison with other approaches

861

$$862 \quad QME = ecdf_{obs}^{-1}(ecdf_{raw}(S(i, t))) \quad [7]$$

863

864 Where:

865 $ecdf_{obs}$ = empirical cumulative distribution function for the gauge based observation

866 $ecdf_{raw}$ = empirical cumulative distribution function for the uncorrected CMORPH

867

868 The advantage of this bias scheme is that it corrects quantiles and preserves the extreme
869 precipitation values (Themeßl et al., 2012). However, it also has its limitation due to the
870 assumption that both the observed and satellite rainfall follow the same proposed distribution,
871 which may introduce potential new biases.

872

873 3.4. Rainfall rates and seasons

874 To assess the performance of SREs for different classes of daily rainfall rates five classes are
875 defined which indicate: very light (< 2.5 mm/day), light (2.5-5.0), moderate (5.0-10.0 mm/day),
876 heavy (10.0-20.0 mm/day) and very heavy rainfall (> 20 mm/day).

877

878 Furthermore, gauged rainfall was ~~based estimates were~~ divided into wet and dry seasonal
879 periods to assess the influence of seasonality on performance of bias correction schemes. The

880 wet season in the Zambezi Basin spans from October-March whereas the dry season spans
881 from April-September.

882

883 3.5. Evaluation of CMORPH estimates

884 Corrected and uncorrected CMORPH satellite rainfall estimates are evaluated with reference
885 to rain-gauge ~~estimates—rainfall—~~ using statistics that measure systematic differences (i.e.
886 percentage bias and Mean Absolute Error (MAE)), measures of association (e.g. correlation
887 coefficient and Nash Sutcliffe Efficiency (NSE)) and random differences (e.g. standard
888 deviation of differences and coefficient of variation) (Haile et al., 2013). Bias is a measure of
889 how the satellite rainfall estimate deviates from the raingauge ~~estimatesrainfall~~, and the result is
890 normalised by the summation of the gauge values. A positive value indicates overestimation
891 whereas a negative value indicates underestimation. The correlation coefficient (ranging
892 between +1 and -1) represents the linear dependence of gauge and CMORPH data. MAE is
893 the arithmetic average of the absolute values of the differences between the daily gauge and
894 CMORPH satellite rainfall estimates. The MAE is zero if the rainfall estimates are perfect and
895 increases as discrepancies between the gauge and satellite become larger. NSE indicates how
896 well the satellite rainfall matches the raingauge observation and it ranges between - ∞ and 1,
897 with NSE = 1 meaning a perfect fit (Nash and Sutcliffe, 1970).

898

899 Equations [8-11] apply.

900

$$901 \quad bias (\%) = \frac{\sum(S-G)}{\sum G} * 100 \quad [8]$$

902

$$903 \quad R = \frac{\sum(G-\bar{G})(S-\bar{S})}{\sqrt{\sum(G-\bar{G})^2}\sqrt{\sum(S-\bar{S})^2}} \quad [9]$$

904

$$905 \quad MAE = \frac{1}{n} \sum |S - G| \quad [10]$$

906

$$907 \quad NSE = \frac{\sum(G-S)^2}{\sum(G-\bar{G})^2} \quad [11]$$

908

909 Where:

910 S = satellite rainfall estimates (mm/day)

911 \bar{S} = mean of the satellite rainfall estimates (mm/day)
912 G = rainfall ~~estimates~~ by a rain gauge (mm/day)
913 \bar{G} = mean values of rainfall recorded by a rain gauge (mm/day)
914 n = number of observations
915

916 **3.6. Test for differences of mean**

917 To detect significant differences between gauge and satellite rainfall (corrected and
918 uncorrected) and differences amongst the five bias correction methods described in Section
919 3.3, we apply paired t-test and analysis of variance (ANOVA) tests.
920

921 *3.6.1. Paired t-tests*

922 A paired t-test was used to test whether there is a significant difference between raingauge,
923 uncorrected and bias corrected CMORPH satellite rainfall for the 52 raingauges. Results are
924 summarized for the Upper, Lower and Middle Zambezi. The paired t-test compares the mean
925 difference of the values to zero. It depends on the mean difference, the variability of the
926 differences and the number of data. The null hypothesis (H_0) is that there is no difference in
927 mean gauge and satellite daily rainfall (uncorrected and bias corrected). If the p-value is less
928 than or equal 0.05 (5%), the result is deemed statistically significant, i.e., there is a significant
929 relationship between the gauge and satellite rainfall (Wilks, 2006; Field, 2009).
930

931 *3.6.2. Analysis of Variance (ANOVA) test*

932 The ANOVA-test aims to test whether there is a significant difference amongst the 5 bias
933 correction techniques. The Null hypothesis (H_0) is that there are no differences amongst the
934 five bias correction schemes. We further determined which schemes differ significantly using
935 3 post-hoc tests, namely: Tukey HSD, Scheffe and the Bonferroni (Brown, 2005; Kucuk et al.,
936 2018). Results are summarized for the Upper, Lower and Middle Zambezi.
937

938 **3.7. Taylor diagram**

939 We apply a Taylor diagram to evaluate differences in data sets generated by respective bias
940 correction schemes by providing a summary of how well bias correction results match gauge
941 ~~based estimates~~ rainfall in terms of pattern, variability and magnitude of the variability. Visual
942 comparison of SRE performance is done by analysing how well patterns match each other in
943 terms of the Pearson's product-moment correlation coefficient (R), root mean square difference

944 (E), and the ratio of variances on a 2-D plot (Lo Conti et al., 2014; Taylor, 2001). The reason
945 that each point in the two-dimensional space of the Taylor diagram can represent the above
946 three different statistics simultaneously is that the centered pattern of root mean square
947 difference (E^i), and the ratio of variances are related by the following:

$$949 \quad E^i = \sqrt{\sigma_f^2 + \sigma_r^2 - 2\sigma_f\sigma_r R} \quad [12]$$

950
951 Where:

952 σ_f and σ_r = standard deviation of CMORPH and rain gauge rainfall, respectively.

953
954 Development and applications of Taylor diagrams have roots in climate change studies
955 (Smiatek et al., 2016; Taylor, 2001) but also has frequent applications in environmental model
956 evaluation studies (Cuvelier et al., 2007; Dennis et al., 2010; Srivastava et al., 2015). Bhatti et
957 al. (2016) propose the use of Taylor Diagrams for assessing effectiveness of SREs bias
958 correction schemes. The most effective bias correction schemes will have data that lie near a
959 point marked 'reference' on the x-axis, relatively high correlation coefficient and low root
960 mean square difference. Bias correction schemes matching gauged based standard deviation
961 have patterns that have the right amplitude.

962

963 **3.8. Quantile-quantile (q-q) plots**

964 A q-q plot is used to check if two datasets (in this case gauge vs CMORPH rainfall) can fit the
965 same distribution (Wilks, 2006). A q-q plot is a plot of the quantiles of the first data set against
966 the quantiles of the second data set. A 45-degree reference line is also plotted. If the satellite
967 rainfall (corrected and uncorrected) has the same distribution as the rainguage, the points
968 should fall approximately along this reference line. The greater the departure from this
969 reference line, the greater the evidence for the conclusion that the bias correction scheme is
970 less effective (NIST/SEMATECH, 2001).

971

972 The main advantage of the q-q plot is that many distributional aspects can be simultaneously
973 tested. For example, changes in symmetry, and the presence of outliers can all be detected from
974 this plot.

975

976 **3.9. Cross validation of bias correction**

977 3.9.1. Spatial cross-validation

978 The spatial cross-validation procedure (hold-out sample) applied in this study, involves the
979 withdrawal of 8 in-situ stations from the sample of 60 when generating bias corrected SREs
980 for all pixels across the study area. Corrected SREs are then compared to the raingauge
981 estimates rainfall of the withdrawn stations to evaluate closeness of match. From the sample of
982 8 we selected 2 stations in the < 250 m elevation zone, 3 stations in the 250-950 m zone and 3
983 stations in > 950 m elevation zone. Stations selected have elevation close to the average
984 elevation zone value and are centred in an elevation zone. This left us with 52 stations for
985 applying the bias correction methods and spatial interpolation. As performance indicators to
986 evaluate results of cross-validation, we use the percentage bias, MAE, Correlation Coefficient
987 and the estimated ratio which is obtained by dividing CMORPH rainfall totals and gauge based
988 rainfall totals for the 1999-2013 period.

989

990 3.9.2. Temporal cross-validation

991 For evaluation of SREs in the time domain we followed (Gutjahr and Heinemann (2013) ~~and~~
992 ~~to omitted~~ rainfall ~~estimates~~ (both from gauge and satellite) for the 1998-1999 hydrological
993 year to remain with 14 years for bias correction of SREs. Bias corrected estimates for the 14
994 years for 1998-1999 are then evaluated against estimates for 1998-1999 for the 14 years period
995 that served as reference. For evaluation we use the percentage bias, MAE, Correlation
996 coefficient and the estimated ratio, that all are averaged for the Upper,
997 Middle and Lower Zambezi but also for the wet and dry seasons.

998

999 4. Results and Discussion

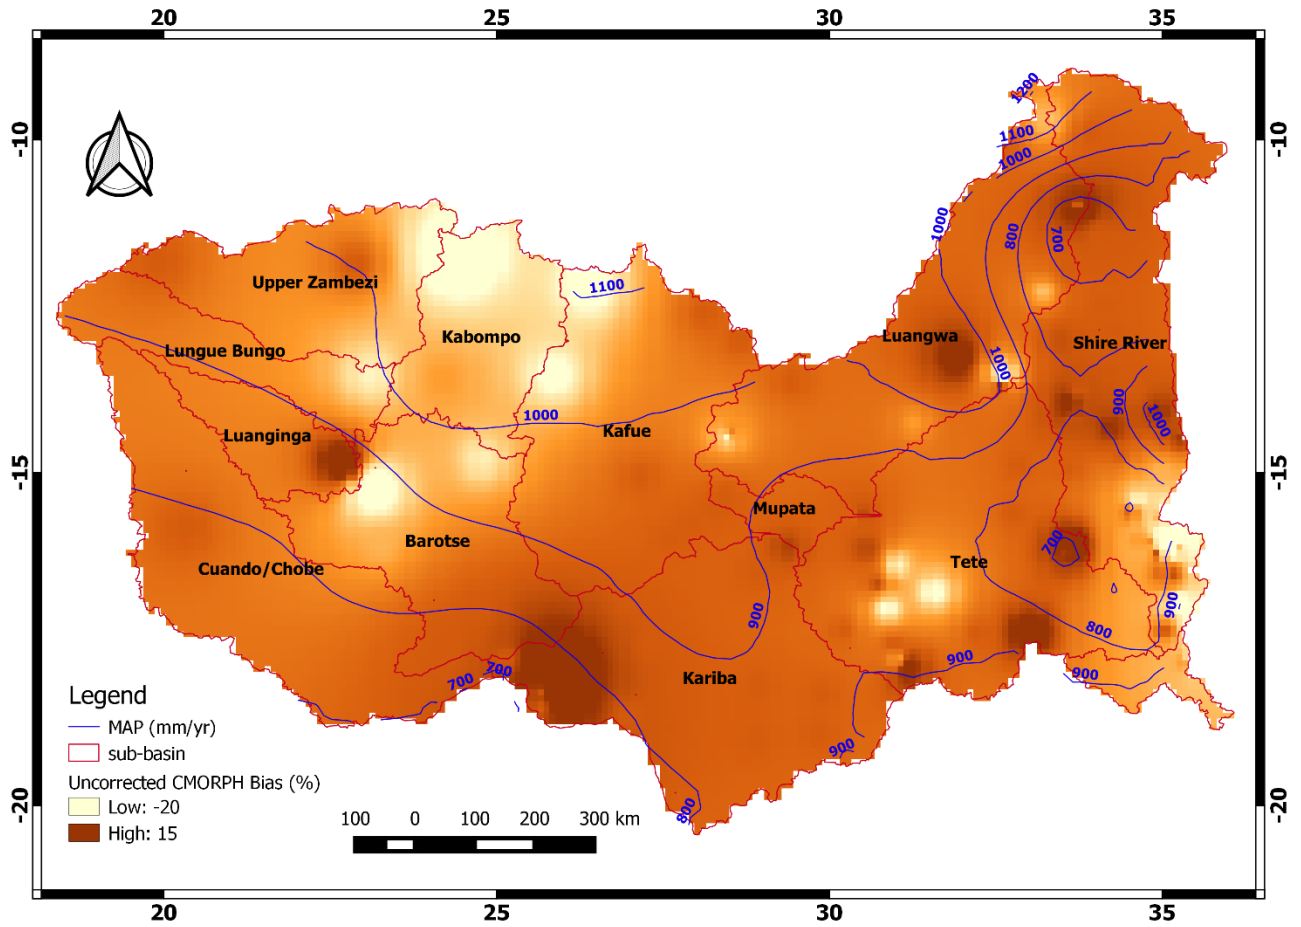

1000

1001 4.1. Performance of uncorrected CMORPH rainfall

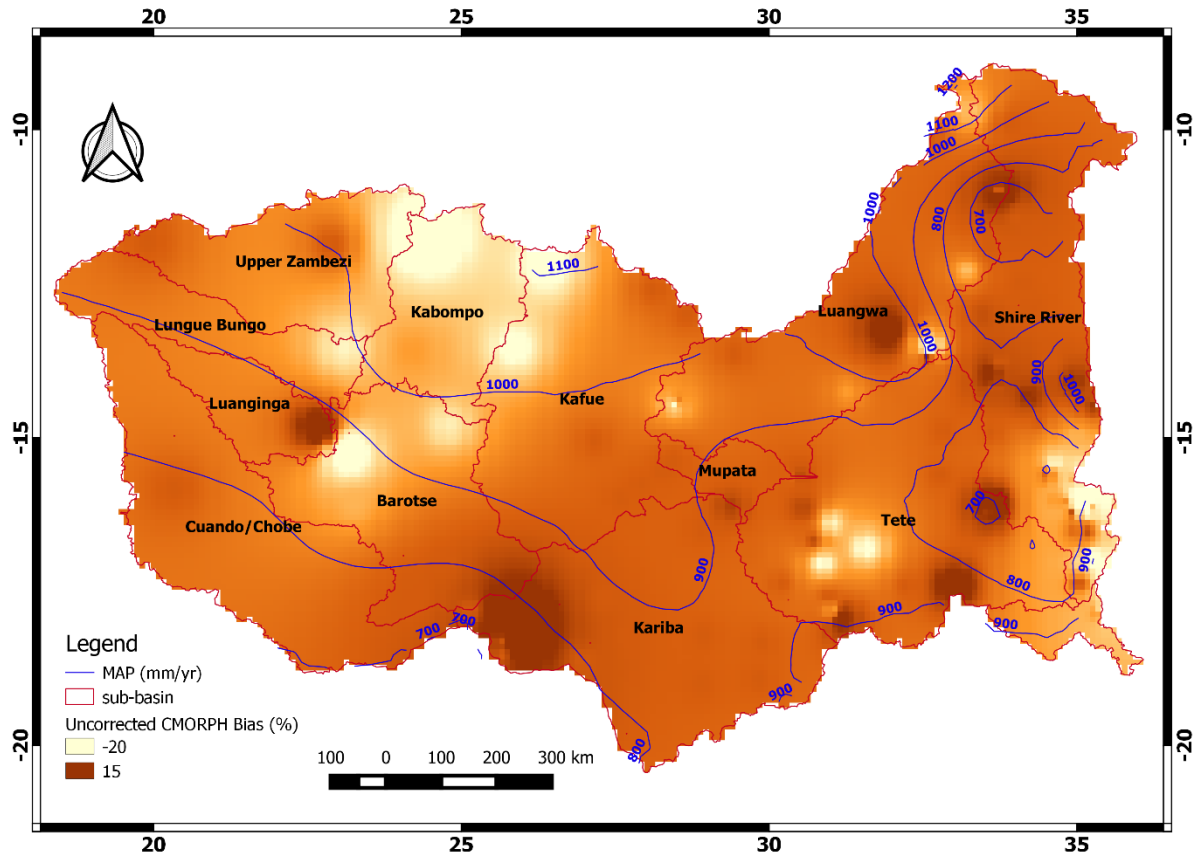

1002 The spatially interpolated values of bias (%) covering across the Zambezi Basin are shown in
1003 Figure 2. Areas in the central and western part of the basin have bias relatively close to zero
1004 suggesting good performance of the uncorrected CMORPH product. However, relatively large
1005 negative bias values (-20 %) are shown in the Upper Zambezi's high elevated areas such as
1006 Kabompo and northern Barotse Basin, in the south-eastern part of the basin such as Shire River
1007 Basin and in the Lower Zambezi's downstream areas where the Zambezi River enters the
1008 Indian Ocean. CMORPH overestimates rainfall locally in Kariba, Luanginga, and Luangwa
1009 basins by positive bias values. As such CMORPH estimates do not consistently provide results

1010 that match [rain gauge](#) observations. Since CMORPH estimates have pronounced error ($-10 >$
 1011 $\text{bias (\%)} > 10$), ~~we first need to remove the~~ bias needs to be removed before the product can
 1012 be applied ~~for~~ hydrological analysis and in water resources applications. Figure 2 also shows
 1013 contours for rain-gauge mean annual precipitation (MAP) in the Zambezi Basin with higher
 1014 values in the northern parts of the basin (Kabompo and Luangwa) compared to ~~the of lower~~
 1015 localised estimates of MAP such as in Shire River and Kariba subbasins.

1016

1017

1018 Figure 2: The spatial variation of bias (%) for gauge vs uncorrected CMORPH daily rainfall (1998-2013) for the Zambezi
 1019 Basin. The gauge based isohyets for Mean Annual Precipitation (MAP) are shown in blue.

1021 **4.2. Effects of elevation and distance from large-scale open water bodies on CMORPH bias**

1024 Figure 3 shows Taylor diagrams with a comparison of basin lumped estimates of daily uncorrected time series (1999–2013) of CMORPH and ~~rain gauge estimates~~ gauge based rainfall for the 3 elevation zones (left panes) and 4 distance zones from large-scale open water bodies (right panes). ~~The purpose of the diagrams is to show if elevation or distance from large-scale open water bodies affect the performance in the CMORPH estimates.~~ Here ~~the performance in~~ CMORPH performance is indicated by means of ~~defined for~~ the root mean square difference (E), correlation coefficient (R) and standard deviation. Figure 3 ~~reveals shows~~ that ~~the~~ standard deviations in the elevation zones and the distance zones (except for the < 10 km distance zone) are lower than the reference/rain-gauge standard deviation which is indicated by the ~~dashed brown~~ black arc (value of 8.45 mm/day). The stations in the high elevation zone (> 950 m) and long distance zone (> 100 km) reveal lower variability than stations at lower elevation and shorter distance zones. With respect to the reference line, CMORPH estimates that are lumped for respective elevation zones and distance to a large water body do not match

1037 standard deviation of rain gauge based counterparts. Figure 3 also ~~reveals~~ shows that CMORPH
 1038 standard deviations that are close to gauge ~~estimates~~ based rainfall belong to lower elevation
 1039 and shorter distance zones. Based on the Taylor diagrams, the statistics (R and E) for
 1040 uncorrected CMORPH show increasing performance for increasing elevation and increasing
 1041 distance from large-scale water bodies. Specifically, stations in the lower elevation zones (<
 1042 250m) have lower R and higher E than the higher elevation zones (> 950 m). ~~The~~ For shorter
 1043 distance zones ~~also have~~ lower R and and higher E is shown than for -longer distance zones (>
 1044 100 km). These findings suggest that in genral effects of distance to large scale water body are
 1045 minimal except for distances <10 km.
 1046

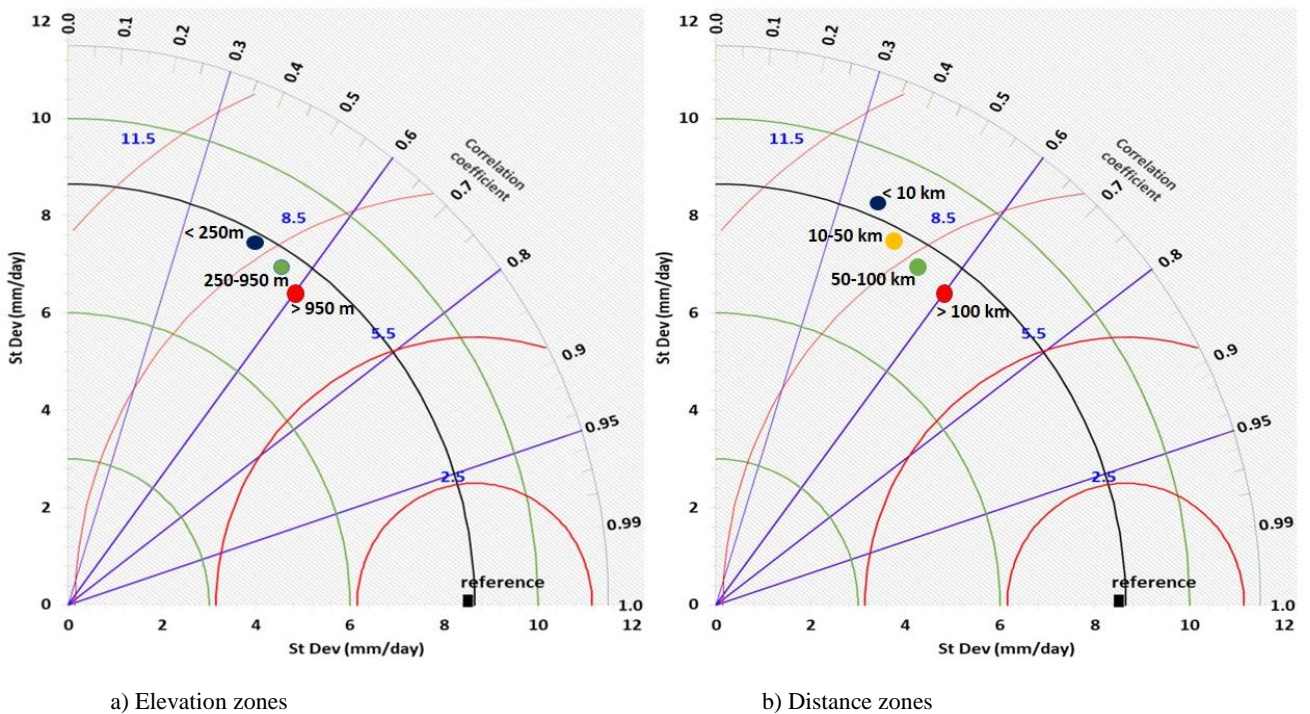

Figure 3. Time series of rain gauge (reference) vs CMORPH estimations, period 1999-2013, for elevation zones (left panes) and distance zones (right panes) in the Zambezi Basin. The correlation coefficients for the radial line denote the relationship between CMORPH and gauge based observations. Standard deviations on both the x and y axes show the amount of variance between the two-time series. The standard deviation of the CMORPH pattern is proportional to the radial distance from the origin. The angle between symbol and abscissa measures the correlation between CMORPH and rain gauge observations. The root mean square difference (red contours) between the CMORPH and rain gauge patterns is proportional to the distance to the point on the x-axis identified as "reference". For details, see Taylor (2001).

1048

1049

1050 **4.3. Evaluation of bias correction**

1051

1052 4.3.1. Standard statistics

1053 Figure 4 shows frequency based statistics (mean and maximum) on accuracy of CMORPH
 1054 rainfall estimates for each bias correction method. The ratio of cumulated estimates (1999-
 1055 2013) -from [raingauge](#) and CMORPH estimates for the Lower, Middle and Upper Zambezi
 1056 subbasins are shown. Results show that the bias of CMORPH moderately reduced for each of
 1057 the five bias correction schemes. However, the effectiveness of the schemes vary spatially with
 1058 best performance in Lower and Upper Zambezi subbasin and relatively poor performance in
 1059 the Middle Zambezi subbasin (see Figure 4).

1060

1061

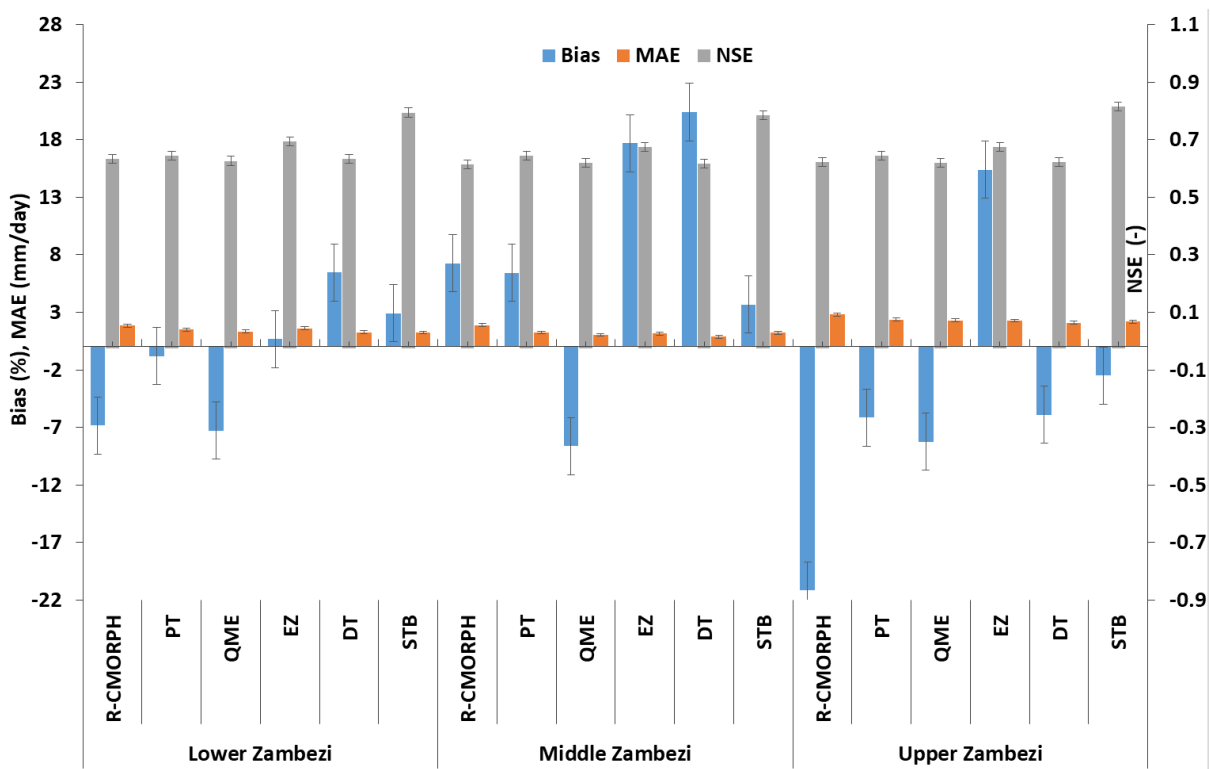

1062 Figure 4: Frequency based statistics (mean, max and estimated ratio of gauged sum vs CMORPH sum for 1999-2013) of
 1063 [corrected CMORPH](#) for [lower, middle and upper the](#) Zambezi Basin.

1064

1065 Judging by the three performance indicators (mean, max and estimated ratio), results indicate
 1066 that STB bias correction scheme is consistently effective in removing CMORPH rainfall bias
 1067 in the Zambezi Basin. STB and PT effectively adjust for the mean of CMORPH rainfall
 1068 estimates. Statistics in Figure 5 confirm these findings especially for the Upper Zambezi
 1069 subbasin where the mean of corrected estimates improved by > 60% from the mean of
 1070 uncorrected estimates. In addition, PT in the Lower Zambezi, QME in both Middle and Upper
 1071 Zambezi and STB in the Upper Zambezi were also effective (improvement by 16 %) in
 1072 correcting for the highest values in the rainfall estimates. STB performs better than other bias
 1073 schemes in reproducing rainfall for the Lower and Upper Zambezi subbasin, where the ratio of
 1074 gauge total to corrected CMORPH total is close to 1.0.

 1085
 1086
 1087

Figure 5 shows the mean absolute error (MAE) and percentage bias (% bias) on the left axis and Nash Sutcliffe Efficiency (NSE) on the right axis. ~~The three performance indicators were used as a measures~~ to evaluate performance of bias correction schemes in the Zambezi Basin. The effectiveness of the bias correction by all schemes varies over the different parts of the basin but is higher in the Lower and Upper Zambezi than in the Middle Zambezi. The STB, PT and EZ shows improved performance by exhibiting smaller MAEs compared to the uncorrected CMORPH (R-CMORPH). A greater improvement is shown for the Middle Zambezi where the uncorrected MAE of 1.89 mm/day is reduced to 0.86 mm/day after bias correction by the elevation zone bias correction scheme (EZ). The signal on improved performance for the Lower and Middle Zambezi as compared to the Upper Zambezi is also evident for the majority of the bias correction techniques. However, relatively large error remains in the MAE.

1088
 1089
 1090
 1091
 1092
 1093
 1094
 1095

Figure 5: Percentage bias, Mean Absolute Error (left axis) and Nash Sutcliffe (NSE) (right axis) of corrected and uncorrected CMORPH (R-CMORPH) daily rainfall averaged for the Lower Zambezi, Middle Zambezi and Upper Zambezi. (put NSE to the right of the numbers)

NSE for STB is above 0.8 for all three Zambezi subbasins. This is followed by EZ with which for all three subbasins s is NSE above 0.7 for the three subbasins. The lowest NSE is for QME which is close to 0.65 for all three subbasins. ~~With regard to reducing bias (% bias), B~~best

1096 results for reducing bias (% bias) are obtained by EZ in the Lower Zambezi (% percentage-bias
 1097 of 0.7 % ~ absolute bias of 0.10 mm/day) and Upper Zambezi (0.22 % ~0.23 mm/day), PT in
 1098 the Lower and Middle Zambezi (-0.84 % ~0.18 mm/day) and STB in all the basins (< 3.70 %
 1099 ~0.24 mm/day). Gao and Liu (2013) over the Tibetan Plateau asserts that EZ (~~a correction~~
 1100 ~~process based on elevation~~) is valuable in correcting systematic biases to provide a more
 1101 accurate precipitation input for rainfall-runoff modelling. Significant underestimation for the
 1102 uncorrected (-21.16 % ~0.44 mm/day) and for bias corrected CMORPH are shown for the
 1103 Upper Zambezi subbasin.

1104

1105 4.3.2. Significance testing

1106 Table 2 shows results of statistical tests to assess whether there is a significant difference ($p <$
 1107 0.05) between raingauge vs uncorrected and bias corrected CMORPH satellite rainfall for each
 1108 of the 52 raingauge stations. Results are summarised for the Upper, Middle and Lower Zambezi
 1109 and in the Zambezi basin. The null hypothesis is rejected for PT (Lower Zambezi), DT (Upper
 1110 Zambezi) and QME (all the 3 sub-basins) since $p < 0.05$. This means that statistically the above
 1111 mentioned bias correction schemes results deviate from the gauge. The null hypothesis is
 1112 accepted for STB and EZ (all ~~t~~-three sub-basins), DT (Lower and Upper Zambezi) and PT
 1113 (Middle and Upper Zambezi), since $p > 0.05$ showing the effectiveness of these bias correction
 1114 schemes. Compared to uncorrected satellite rainfall (R-MORPH), results also reveal that the
 1115 bias corrected satellite rainfall is closer to the gauge based estimates rainfall.

1116

1117 Table 2: Paired t-tests for the Upper, Middle and Lower Zambezi. The mean difference is significant at the 0.05 level. Bold
 1118 shows significant values..

Basin	Rainfall Estimate	t-value	Mean Std. Error	p-value (0.05)
Lower Zambezi	R-CMORPH	8.95	0.04	0.04
	DT	39.86	0.09	0.35
	PT	21.08	0.04	0.03
	QME	23.99	0.04	0.04
	EZ	36.43	0.03	0.27
	STB	14.7	0.04	0.46
Middle Zambezi	R-CMORPH	3.27	0.03	0.001
	DT	41.9	0.07	0.24
	PT	26.02	0.03	0.14
	QME	18.38	0.03	0.00
	EZ	26.60	0.02	0.07
	STB	23.6	0.03	0.09

Upper Zambezi	R-CMORPH	4.28	0.08	0.00
	DT	22.63	0.14	0.01
	PT	12.98	0.07	0.05
	QME	13.27	0.07	0.00
	EZ	13.73	0.07	0.14
	STB	13.62	0.07	0.08

1119

1120 *4.3.3. Analysis of variance (ANOVA test)*

1121 The ANOVA test is similar to a t-test except that the test can be used to compare the mean
1122 values from three or more data samples. Results of ANOVA shows that there is a significant
1123 ($p < 0.05$) difference in the mean values of the 5 bias correction results across the three
1124 subbasins. This warranted the running of a post-hoc test to determine which schemes differ
1125 significantly. The contingency matrix in Table 2 shows results of the post-hoc tests results
1126 summarized for the Tukey HSD, Scheffe and the Bonferroni methods but also for the Upper,
1127 Lower and Middle Zambezi. Table 3 also show that STB, PT and EZ are significantly different
1128 from the distribution transformation technique (DT) for the three sub-basins. STB, the best
1129 performing bias correction scheme identified using majority of the indicators, is also
1130 significantly different from QME and EZ. QME which has poorly performed is significantly
1131 different from EZ. Results are important for further application of the bias correction schemes
1132 for studies such as flood, drought and water resources modelling.

1133

1134 Table 3: ANOVA post-hoc tests for the results of the five bias correction schemes ($p < 0.05$). The checklist table gives a
1135 indication (symbol) where two bias correction scheme's results are significantly different from each other. Where there is no
1136 symbol, it means that the schemes' results are not significantly different. The different symbols represent the Upper, Middle
1137 and Lower Zambezi basins.

1139

1140

1141 *4.3.4. Taylor Diagrams*

1142 Figure 6 shows the Taylor diagram for time series of rain gauge (reference) observations vs
1143 CMORPH bias correction schemes averaged for the Lower Zambezi (UZ), Middle Zambezi

1144 (MZ) and Upper Zambezi (UZ). Absolute values used to develop the Taylor diagram are shown
1145 in Appendix 2. The position of each bias correction scheme and uncorrected satellite rainfall
1146 (R-MORPH) on Figure 6 shows how closely the rainfall by [uncorrected CMORPH \(R-](#)
1147 [MORPH\)](#) matches rain-gauge observations as well as effectiveness of each of the bias schemes.
1148 Overall, all bias correction schemes show intermediate performance in terms of bias removal.
1149 Only the PT and STB for the Lower Zambezi subbasin lie on the line of standard deviation
1150 (brown dashed arc) and means the standard deviation of the data for the two bias correction
1151 schemes matches the gauge observations. This also indicates that rainfall variations after PT
1152 and STB bias correction for the Lower Zambezi resembles gauge based standard deviation.
1153 Note however that STB performs better than EZ as shown by the superior correlation
1154 coefficient. Compared against the reference line of mean standard deviation (8.5 mm/day), the
1155 rainfall standard deviation for most bias correction schemes is below this line and as such
1156 exhibit low variability across the Zambezi Basin.

1157

1158 Figure 6 also shows that most of the bias correction schemes have standard deviation range of
1159 6.0 to 8.0 mm/day. There is a consistent pattern between the bias correction schemes that have
1160 low R and high RMSE difference indicating that these schemes are not effective in bias
1161 removal. Overall, the best performing bias correction schemes (STB and EZ) have $R > 0.6$,
1162 standard deviation relatively close to the reference point and $RMSE < 7$ mm/day. The
1163 uncorrected CMORPH (R-MORPH) lies far away from the marked reference (gauge) point on
1164 the x-axis suggesting an intermediate overall effectiveness of the bias correction schemes such
1165 as STB, EZ, DT and PT in removing error as they are relatively closer to the marked reference
1166 point.

1167

1168

1169 Figure 6: Taylor's diagram on Rain gauge (reference) observations and CMORPH bias corrected estimates (all 5 schemes) as
 1170 averaged for the Lower Zambezi (LZ), Middle Zambezi (MZ), and Upper Zambezi (UZ) for the period 1999-2013. The
 1171 distance of the symbol from point (1, 0) is also a relative measure of the bias correction scheme performance. The position of
 1172 each symbol appearing on the plot quantifies how closely precipitation estimates by respective bias correction scheme's
 1173 matches counterparts by rain gauge. The dashed blue lines indicate the root mean square difference (mm/day).

1174

1175 The least performing bias correction scheme is QME with relatively large RSMD (> 8 mm/day)
 1176 and with low R (< 0.49) and standard deviation (< 6.5 mm/day). Inherent to the methodology
 1177 of most of bias correction schemes (e.g. QME) is that the spatial pattern of the SRE does not
 1178 change and therefore ~~the~~ R for a specific station for daily precipitation does not necessarily
 1179 improve. The bias correction results by the Taylor Diagram in Figure 6 corroborates with
 1180 findings shown in Figure 4 and Figure 5 for mean, max, ratio of rainfall totals and bias as
 1181 performance indicators.

1182

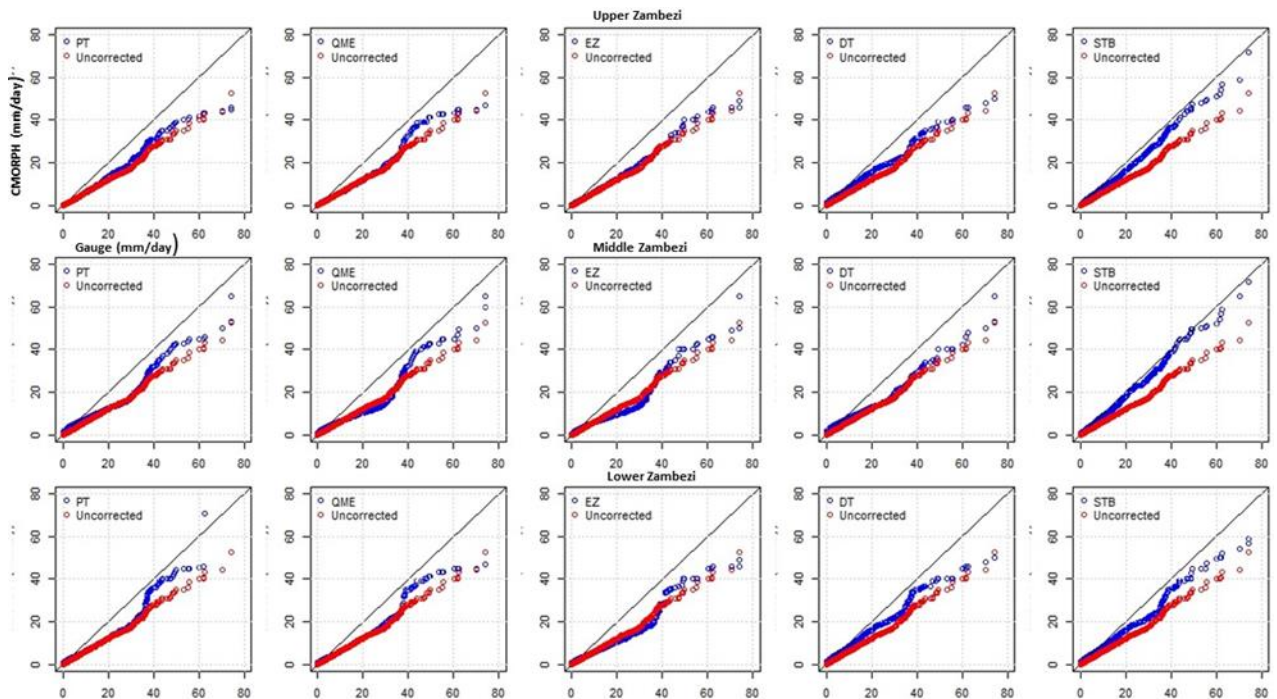

1183 4.3.5. q-q plots

1184 Figure 7 shows q-q plots for the Upper, Middle and Lower Zambezi for gauge rainfall against
 1185 uncorrected and bias corrected CMORPH rainfall. Results show that the STB q-q plots for bias

1186 corrected CMORPH across the 3 basins has majority of points that fall approximately along
 1187 the 45-degree reference line. This means that the STB bias corrected satellite rainfall has closer
 1188 distribution to the raingauge as compared to the uncorrected CMORPH counterparts suggesting
 1189 effectiveness of the bias correction scheme. Other bias correction schemes such as QME, EZ
 1190 and PT have data points showing a greater departure from the 45-degree reference line so
 1191 performance is less effective.

1192
 1193 In some instances in both the Upper, Middle and Lower Zambezi, bias corrected values are
 1194 significantly higher than the corresponding gauge values whereas in some instances there is
 1195 serious underestimation. All q-q plots also show that for all bias correction schemes, the
 1196 differences between gauge and satellite rainfall are smallest minimal for low rainfall rates (<
 1197 2.5 mm/day) and increasing for heavy rainfall (> 20.0 mm/day). In more detail, all the bias
 1198 correction schemes show a larger difference for the transition area from low to heavy rainfall.
 1199 QME and PT are not in good agreement with the rest of the bias correction schemes for higher
 1200 rainfall estimates (40 and 60 mm/day).

1201

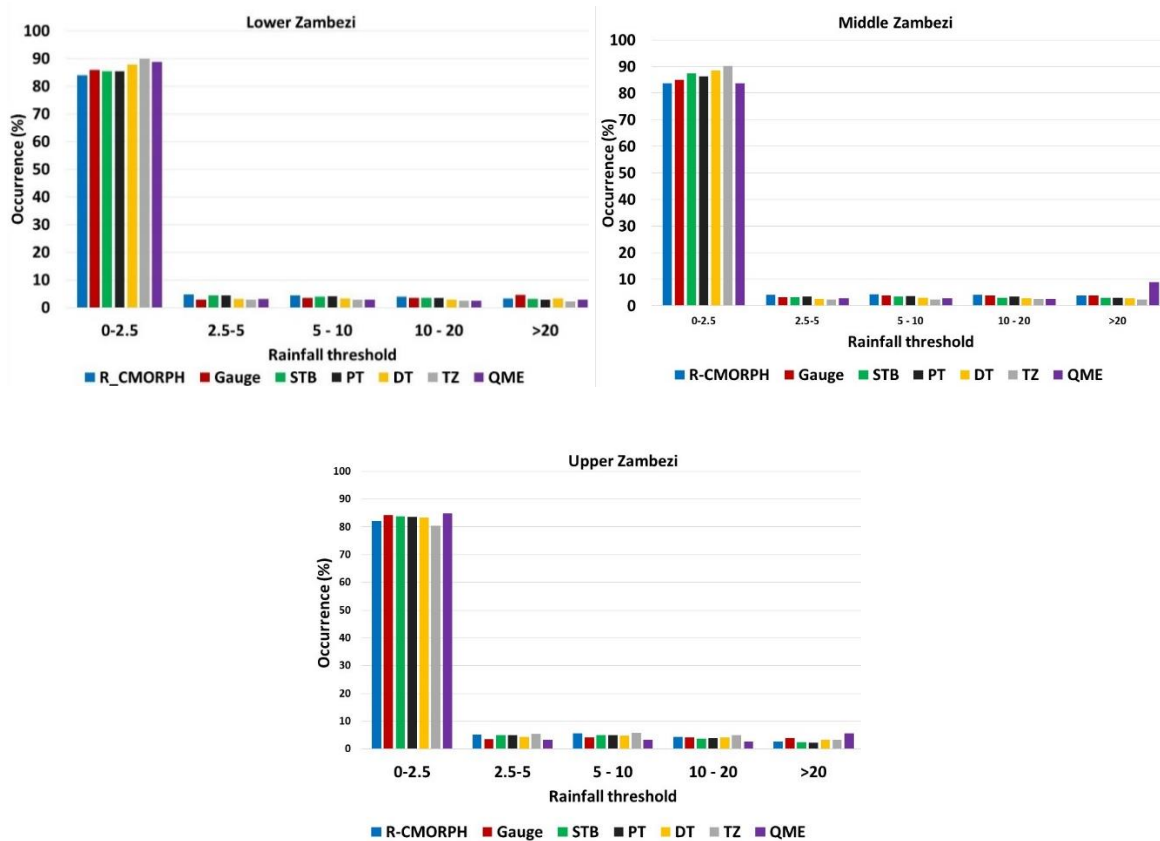

1202
 1203 Figure 7: q-q plot for gauge vs satellite rainfall (corrected and bias corrected) for the Upper (top panes),
 1204 Middle (middle panes) and Lower (bottom panes) Zambezi.

1205

1206 **4.3.6. CMORPH rainy days**

1207 Occurance (%) of rainfall rates in the Zambezi Basin for each bias correction scheme is shown
 1208 in Figure 8. The highest percentage (80-90 %) is shown for very light rainfall (0.0-2.5 mm/day).
 1209 A smaller percentage is shown for 2.5-5.0 mm/day which is the light rainfall class. Smallest
 1210 percentage (< 5%) is shown for heavy rainfall (> 20.0 mm/day). The CMORPH rainfall
 1211 corrected with STB, PT and DT matches the gauge based rainfall (%) in the Lower, Middle
 1212 and Upper Zambezi suggesting good performance. All five bias correction schemes in the
 1213 Zambezi Basin generally tend to overestimate low rainfall (< 2.5 mm/day). There is a small
 1214 difference for moderate rainy days classification of 10.0-20.0 mm/day. For QME in the Middle
 1215 and Upper Zambezi, there is overestimation by > 80 %. There is underestimation of rainfall
 1216 greater than 20 mm/day.

1217

1218
1219

Figure 8: Percentage occurrence for rainfall rate classes

1220
1221
1222

1223 Figure 9 gives the bias correction performance for the different rainy day classes. Results of
 1224 bias removal varies for the Lower, Middle and Upper Zambezi. Comparatively, the STB and
 1225 EZ show effectiveness in bias removal with an average bias correction of 0.97 % and 3.6 % in
 1226 the whole basin respectively. Results show more effectiveness in reducing the percentage bias
 1227 for light rainfall and moderate rainfall (0-2.5 and 5.0-10.0 mm/day) than the high to very high

1228 rainfall (10.0-20.0 mm/day and >20.0 mm/day) across the whole basin. ~~The poor performance~~
 1229 ~~of correction for the heavy rainfall class is caused by, sometimes, large mismatch of high rain~~
 1230 ~~gauge values versus low CMORPH values. This leads to unrealistically high CMORPH values~~
 1231 ~~which remain poorly corrected by bias schemes.~~

1232

1233

1234 Figure 9: Bias correction (%) for respective rainfall rate classes

1235

1236 **4.4. Spatial cross-validation**

1237 Table 4 shows the cross-validation results on bias correction for 8 [raingauge](#) stations ~~for in the~~
 1238 wet and dry seasons. It is evident that CMORPH has a considerable bias, although this bias is
 1239 not always consistent for all 8 validation stations. Overall, Mutarara station has the highest
 1240 positive bias (overestimation) whereas Makhanga has the highest negative bias
 1241 (underestimation) for uncorrected CMORPH. Bias is effectively being removed by the STB
 1242 followed by the EZ bias correction schemes. Bias is more effectively removed for the wet
 1243 season than for the dry season. For the dry season, the STB shows good performance for
 1244 Mkhanga and Nchalo stations, whereas good performance is shown for Kabompo and Chichiri
 1245 stations. However, the MAE is higher for the wet season than for the dry season. Correlation
 1246 coefficient for bias corrected satellite rainfall is higher for the wet season than for the dry
 1247 season. ~~The study by Ines and Hansen (2006) for semi arid eastern Kenya showed that~~

1248 multiplicative bias correction schemes such as STB were effective in correcting the total of the
 1249 daily rainfall grouped into seasons. Our results show that effectiveness in bias removal in the
 1250 wet season is higher than in the dry season. This is contrary to Vernimmen et al. (2012) who
 1251 showed that for the dry season, bias for PT decreased in Jakarta, Bogor, Bandung, East Java
 1252 and Lampung regions after bias correction of monthly TMPA 3B42RT precipitation estimates
 1253 over the period 2003–2008. Habib (2014) evaluated sensitivity of STB for the dry and wet
 1254 season and concluded that the bias correction factor for CMOPRH shows lower sensitivity for
 1255 the wet season as compared to the dry season. Our findings also reveal that bias factors for all
 1256 the schemes are more variable in the dry season than in the wet season and lead to poor
 1257 performance of the bias correction schemes in the dry season.

1258
 1259 Validation results for all 8 stations for the period 1999–2013 show that the bias on CMORPH
 1260 reduces the MAE by 23 %. This represents 22 % of the average MAE estimated using 52
 1261 raingauges. Since the stations used for validation are different from the stations used to develop
 1262 the bias correction procedures, we conclude that the results are independent of deliberate efforts
 1263 to reducing the errors. Similar cross-validation techniques where measures of performance are
 1264 evaluated using a sample that was not included in the calibration of the correction procedure
 1265 gave good performance in the the state of Rhineland-Palatinate in Europe (Gutjahr and
 1266 Heinemann, 2013).

1267
 1268 Table 4: Cross validation results for the bias correction procedure with 8 gauging stations for the dry and wet season. Stations
 1269 lie at average elevation zone and sort of centred in an elevation zone. R-Morph is the uncorrected R-CMOPRH estimate. DT,
 1270 PT, QME, EZ and STB are the bias corrected rainfall estimate. Bold values indicate best performance. * = zone 1: elevation
 1271 of < 250 m , ** = zone 2: elevation range of 250 - 950 m and *** = zone 3: elevation > 950 m

1272

1273 4.5. Temporal cross-validation

1274 The same performance indicators in spatial cross-validation are calculated for the temporal
1275 cross-validation. Results are presented in Table 5. [The structure of the error is the same as in](#)

1276 ~~Table 4, where the MAE is higher for the wet season than for the dry season. However,~~
1277 ~~compared to the spatial cross validation~~ †The difference in effectiveness in the error removal
1278 between the dry and wet season is much larger ~~due to the limited length~~ What influence does
1279 the length have on effectiveness in terms of MAE? A short or long length (n) both may give a
1280 low or high MAE of the time series (1998-1999). STB outperforms both bias correction
1281 methods but does also have problems correcting the estimated ratios. After the correction, the
1282 correlation coefficient is much improved. The fact that MAE remains relatively large indicates
1283 ~~z~~ that errors remain locally large. These values are almost in same range to performance
1284 indicators obtained from the main performance assessment period (1999-2013). ~~However using~~
1285 ~~one year (1998-1999) to correct bias in CMORPH increased the MAE by 10% compared to~~
1286 ~~the main performance assessment period (1999-2013).~~ The estimated ratio adjustment shows
1287 improvement for the Middle Zambezi than for the Lower and Upper Zambezi in the temporal
1288 cross-validation reduced by 7% from the 1999-2013 period.

We present methods to assess the performance of bias correction schemes for CMORPH rainfall estimates in the Zambezi River Basin. For correction we applied sequential windows of 7 days that count 5 rainy days with rainfall threshold of 5 mm. Firstly we aimed to evaluate if performance of CMORPH rainfall is affected by elevation and distance from large scale open water bodies. Results in Taylor diagrams show that effects of distances > 10 km are minimal in this study. For distance < 10 km results in the same Taylor diagrams shows some effect with increased CMORPH estimation errors although not clearly identifiable by the limited number of gauging stations at distance < 10 km. We advocate further study on this aspect since the gauge network we relied on was not specifically designed for this purpose of analysis.

~~Our results show that aspects of elevation and distance from large scale open water bodies are distinctively represented (clear signature) in the relationship between CMORPH and gauge rainfall in the Zambezi Basin.~~ For elevation, Romilly and Gebremichael (2011) showed that the accuracy of CMORPH at monthly time base is related to elevation for six river basins in Ethiopia. A similar finding was reported by ~~(e.g. Haile et al. (2009), Katirai-Boroujerdy et al., (2013), Rientjes et al. (2013a) and Wu and Zhai (2012)~~ who found that performance of CMORPH is affected by elevation. ~~s.~~ Contrary to these findings, Vernimmen et al. (2012) concluded that TRMM Multi-satellite Precipitation Analysis (TMPA) 3B42RT performance was not affected by elevation ($R^2 = 0.0001$) for Jakarta, Bogor, Bandung, Java, Kalimantan and Sumatra regions (Indonesia). The study by Gao and Liu (2013) showed that the bias in CMORPH rainfall over the Tibetan Plateau is affected by elevation. Whilst distance from large scale open water bodies and elevation have been assessed separately for this study, Habib et al. (2012a) revealed that both aspects the two (distance from large scale open water bodies and elevation) interact in the Nile Basin to produce unique circulation patterns to affect the performance of SRE.

~~We note that the overall performance could also be affected among other things by the sparse and irregular distributed rain gauges in the Zambezi Basin.~~

1325 Secondly we evaluate the effectiveness of linear/non-linear and time-space variant/invariant
1326 bias correction schemes. The bias correction results by means of performance indicators such
1327 as Taylor Diagrams, -q-q plots, ANOVA and standard statistics such as mean, max, ratio of
1328 rainfall totals and bias reveal that the STB is the best bias correction method. This method
1329 forces the estimates to behave as observations b-y its nature, consider correction only for spatial
1330 distributed patterns in bias, commonly known as space variant/invariant and thus forces the
1331 estimates to behave as observations. We did not investigate effects of the applied sequential
1332 windows of 7 days for each bias correction scheme but note that other window lengths could
1333 yield more favarable results for bias schemes likesuch as PT, DT and QME that commomnly
1334 rely on larger sample sizes. —As alluded to by Habib (2013), correction should improve
1335 hydrological applications by improved rainfall representation. This we saw in the applies to
1336 Zambezi basin as well where improved rainfall representation by STB is desirable with
1337 demands for more applications of the product (such as for in-drought analysis, flood prediction,
1338 weather forecasting and rainfall runoff modeling). The study is unique as we assess the
1339 importance of space and time aspects of CMORPH bias for rainfall-runoff modeling in a data
1340 scarce catchment. Findings in this study on cross and temporal validation Our findings
1341 contribute to efforts that aim towards enhancing the real-world applicability of satellite rainfall
1342 products. The study site is the Zambezi Basin-an example of many world regions that can
1343 benefit from satellite-based rainfall products for resource assessments and monitoring.
1344 ~~As alluded to by Habib (2013), correction should improve hydrological applications by~~
1345 ~~improved rainfall representation. This we saw in the Zambezi basin where improved rainfall~~
1346 ~~representation by STB is desirable for more applications of the product (such as in drought~~
1347 ~~analysis, flood prediction, weather forecasting and rainfall runoff modeling). The study is~~
1348 ~~unique as we assess the importance of space and time aspects of CMORPH bias for rainfall-~~
1349 ~~runoff modeling in a data scarce catchment. Our findings contribute to efforts that aim towards~~
1350 ~~enhancing the real world applicability of satellite rainfall products. The study site is the~~
1351 ~~Zambezi Basin-an example of many world regions that can benefit from satellite based rainfall~~
1352 ~~products for resource assessments and monitoring.~~
1353
1354 Thirdly, an assessment of the performance of bias correction schemes to represent different
1355 rainfall rates and climate seasonality is presented. Our findings show that bias is most
1356 overestimated for the very light rainfall (< 2.5 mm/day), which is also the range that shows the
1357 best bias reduction, which in turn is most effective during the wet season. Results also show

1358 that there is underestimation of rainfall greater than 20 mm/day. The poor performance of
1359 correction for the heavy rainfall class is caused by, sometimes, large mismatch of high rain
1360 gauge values versus low CMORPH values. This leads to unrealistically high CMORPH values
1361 which remain poorly corrected by bias schemes. Results are consistent with findings by Gao
1362 and Liu (2013) in the Tibetan Plateau who also found consistent under and overestimation of
1363 occurrence by CMORPH for rainfall rates >10.0 mm/day. A study by Zulkafli et al. (2014) in
1364 French Guiana and North Brazil noted that the low sampling frequency and consequently
1365 missed short-duration precipitation events between satellite measurements results in
1366 underestimation, particularly for heavy rainfall.

1367
1368 Lastly, spatial and temporal cross validation reveal effectiveness of bias correction schemes.
1369 The hold-out sample of 8 stations in this work showed the applicability of different bias
1370 correction methods under different geographical space (spatial). —There is improved
1371 performance of satellite rainfall ~~is higher~~ for the wet season than for the dry season
1372 based on correlation coefficient and MAE. The study by Ines and Hansen (2006) for semi-arid eastern
1373 Kenya showed that multiplicative bias correction schemes such as STB were effective in
1374 correcting the total of the daily rainfall grouped into seasons. Our results show that
1375 effectiveness in bias removal in the wet season is higher than in the dry season This is contrary
1376 to Vernimmen et al. (2012) who showed that for the dry season, bias- for PT decreased in
1377 Jakarta, Bogor, Bandung, East Java and Lampung regions after bias correction of monthly
1378 TMPA 3B42RT precipitation estimates over the period 2003–2008. Habib (2014) evaluated
1379 sensitivity of STB for the dry and wet season and concluded that the bias correction factor for
1380 CMOPRH shows lower sensitivity for the wet season as compared to the dry season. Our
1381 findings also reveal that bias factors for all the schemes are more variable in the dry season
1382 than in the wet season and lead to poor performance of the bias correction schemes in the dry
1383 season.

1384

1385

1386 6. Conclusions

1387

1388 We present methods to assess the performance of bias correction schemes for CMORPH
1389 rainfall estimates in the Zambezi River Basin. —In this study ~~threefour~~ cConclusions of this
1390 study areare drawn:

- 1391 1. Analysis on gauge and CMORPH rainfall estimates shows that performance increases for
1392 higher elevation (>950 m) in the Zambezi Basin and that CMORPH has largest mismatch
1393 at low elevation. Such analysis was established for rain gauges within elevation classes of
1394 < 250 m, 250 - 950 m and > 950 m. The match between gauge and CMORPH estimates
1395 improved at increasing distance to large-scale open water bodies. ~~(poorest for short~~
1396 ~~distances)~~. This was established for rain gauges located within specified distances of ~~< 10~~
1397 ~~km,~~ 10 -50 km, 50 -100 km and > 100 km to a large scale open water body. For distances
1398 < 10 km errors by CMORPH increased but we advocate further study with specifically
1399 designed gauging network for the research purpose.
1400
- 1401 2. For each of the five bias correction methods applied, accuracy of the CMORPH satellite
1402 rainfall estimates improved. Assessment through standard statistics, Taylor Diagrams, t-
1403 tests, ANOVA and q-q plots ~~reveal~~ shows that STB that accounts ~~for~~ space and time
1404 variation of bias, is found more effective in reducing rainfall bias in the basin than the rest
1405 of the bias correction schemes. This indicates that the temporal aspect of CMORPH bias is
1406 more important than the spatial aspect in the Zambezi Basin. Quantile-quantile (q-q) plots
1407 for all the bias correction schemes ~~show,~~ in general show, that bias corrected rainfall is
1408 in good agreement with gauge based ~~estimates rainfall~~ for low rainfall rates but that high
1409 rainfall rates are largely overestimated.
1410
- 1411 ~~3. Evaluation of results by the five bias correction schemes was successfully performed using~~
1412 ~~spatial and temporal cross validation. The hold out sample of 8 stations in this work~~
1413 ~~showed the applicability of different bias correction methods under different geographical~~
1414 ~~space (spatial). It is noted that the relatively short time series used for temporal validation~~
1415 ~~may have affected results.~~
1416
- 1417 4.3. Differences in the mechanisms that drive precipitation throughout the year could result in
1418 different biases for each of the seasons, which motivated us to calculate the bias correction
1419 factors for ~~dry and wet each of the~~ seasons separately. As such CMORPH rainfall time
1420 series were divided ~~into wet and dry seasonal periods~~ to assess the influence of seasonality
1421 on performance of bias correction schemes. Overall, the bias correction schemes reveal that
1422 bias removal is more effective in the wet season than in the dry season.
1423

1424 [5.4](#). We assessed whether bias correction varies for different rainfall rates of daily rainfall in
1425 the Zambezi Basin. There is overestimation of very light rainfall (< 2.5 mm/day) and
1426 underestimation of very heavy rainfall (>20 mm/day) after application of the bias correction
1427 schemes. Bias was more effectively reduced for very low to moderate rainfall (< 2.5 and
1428 5.0-10.0 mm/day) than for high to very high rainfall (10.0-20.0 mm/day and >20.0
1429 mm/day). Overall, the STB and EZ more consistently removed bias in all the rainy days
1430 classification compared to the three other bias correction schemes. Effects of length of
1431 sequential window sizes for selected bias correction schemes is not investigated but
1432 different length possibly could yield more favourable results for PT, QME and DT bias
1433 correction schemes.

1434
1435 Analysis serve to improve reliability of SREs applications in hydrological analysis and water
1436 resource applications in the Zambezi basin such as in drought analysis, flood prediction,
1437 weather forecasting and rainfall runoff modelling. -In follow-up studies, we aim at hydrologic
1438 evaluation of bias corrected CMORPH rainfall estimates at the headwater catchment of the
1439 Zambezi River.

1440

1441 **Acknowledgements**

1442 The study was supported by WaterNet through the DANIDA Transboundary PhD Research in
1443 the Zambezi Basin and the University of Twente's ITC Faculty. The authors acknowledge the
1444 University of Zimbabwe's Civil Engineering Department for platform to carry out this
1445 research.

1446

1447 **Author Contributions**

1448 Webster Gumindoga was responsible for the development of bias correction schemes in the
1449 Zambezi basin and research approach. Tom Rientjes and Alemseged Haile were responsible
1450 for synthesising the methodology and made large contributions to the manuscript write-up.
1451 Hodson Makurira provided some of the rain gauge data and related findings of this study to
1452 previous work in the Zambezi Basin. Reggiani Paulo assisted in interpretation of bias
1453 correction results.

1454

1455

1456 **Conflict of Interests**

1457

1458 The authors declare no conflict of interests.

Appendix 2: Bias correction scheme based Taylor Diagram performance indicators (correlation coefficients, standard deviations and RMSE) of rain gauge (reference) vs CMORPH estimations (corrected and uncorrected), period 1998-2013, for Lower, Middle and Upper Zambezi Basin.

Subbasin	Rainfall estimate	RMSE (mm/day)	Correlation Coefficient	Standard Deviation (mm/day)
	Gauge			9.38

Lower Zambezi	R-CMORPH	9.98	0.46	8.00
	PT	10.41	0.57	8.52
	QME	9.15	0.55	6.98
	EZ	10.48	0.62	6.35
	DT	9.30	0.56	6.55
	STB	8.59	0.72	7.17
Middle Zambezi	Gauge			7.94
	R-CMORPH	8.12	0.49	7.44
	PT	7.87	0.62	6.84
	QME	7.51	0.60	6.00
	EZ	10.69	0.65	6.93
	DT	8.04	0.59	6.96
	STB	7.49	0.76	6.81
Upper Zambezi	Gauge			8.29
	R-CMORPH	7.23	0.45	6.60
	PT	7.97	0.62	7.29
	QME	8.05	0.55	7.12
	EZ	11.50	0.60	8.13
	DT	7.85	0.55	6.45
	STB	0.54	0.74	7.29
