

We thank the two anonymous reviewers and the editor for your extensive general and specific comments that addressed important issues which help us to improve the quality of the manuscript significantly.

5 Anonymous Referee #1

Although one of the major issues of the first round of reviews (style and language) has improved, I stopped reviewing the manuscript after reading the Abstract and the Introduction. There are still too many issues that need correction, even if most of them could be considered as minor, like the usage of not introduced abbreviations in the Abstract, wrong format of citations, spelling of the term "River" etc. and a few grammatically incorrect sentences. This is really a pity, because content-wise the manuscript has a good potential to be published, but such issues should not occur in a manuscript submitted after the first revisions.

Anonymous Referee #2

15 The paper improved substantially and the comments have been addressed adequately, though some questions remain (see comments in file attached). However, the spelling and grammar is still inadequate. We stopped correcting the mistakes after the first sections, because it was too tedious.

This was already commented by both previous reviewers. The authors responded: "accepted and the authors tried at their best to improve the quality of the language significantly." This is, however, not enough for a scientific paper. Please let a native speaker review the paper before the next submission.

Response from the authors:

25 All comments from both referees and from the editor which focused on the language, spelling and grammar usage are accepted. We have tried to improve the language substantially and corrected the spelling errors and grammatically incorrect sentences to our best. Here, we would like to mention that the manuscript has been proofread by the native speaker as well. The corrections and improvements made for the specific and general comments from the two anonymous referees have shown in the  
30 markedup manuscript as below.

**Abstract:** Understanding the response of land use/land cover (LULC) change and climate change to the streamflow of the Nile River has become a priority issue for water management and water resource utilization ~~in~~of the Nile basin. This study assesses the long-term trends of rainfall and streamflow to ~~analyse~~analyze the ~~response~~effect of LULC and climate changes on the hydrology of the ~~study area~~Upper Blue Nile River basin. The Mann-Kendal (MK)~~-~~ test showed ~~—~~ statistically insignificant ~~—~~ increasing trends for annual, monthly, and long rainy~~—~~season rainfall series ~~whereas~~ no trend for daily, short rainy, and dry season rainfall series appeared. However, the Pettitt test ~~failed to~~could not detect any jump point in basin-wide rainfall series except for daily rainfall time series. In contrast, ~~the result of the~~ MK ~~-~~ test's result for daily, monthly, annual, and seasonal (long and short rainy season and dry season) time~~—~~series streamflow showed a statistically significant positive trend ~~and the trend magnitude is statistically significant~~. Landsat satellite images for 1973, 1985, 1995, and 2010 were used for LULC change ~~—~~ detection analysis. The LULC change ~~—~~ detection findings indicate significant~~that~~ expansion of cultivated land area and the reduction of forest coverage ~~were significant~~ before ~~the period~~1995—period. After 1995, the forest coverage ~~began to~~increased while the amount of cultivated land diminish~~—~~getting reduced. Statistically, forest coverage changed from 17.4 % to 14.4 %, 12.2 % and 15.6 % while cultivated land changed from 62.9 % ~~—~~to 65.6 %, 67.5 % and 63.9 % ~~—~~from 1973 to 1985, in 1995, and in 2010 respectively. The hydrological ~~—~~ model result showed that mean annual streamflow increased by 16.9 % between the 1970s and the 2000s due to the combined effect of LULC and climate change. The ~~single~~isolated effect of LULC change on streamflow analysis suggested that LULC change affects surface ~~run-off~~runoff and base flow. This could be attributed to the 5.1 % reduction in forest coverage and 4.6 % increase in cultivated land area. Effects of climate change revealed that the increased rainfall intensity and number of extreme rainfall events from 1971 to 2010 have significantly affected the surface ~~run-off~~runoff and base flow. The ~~single~~isolated impacts of climate change are ~~is~~ more significant as compared to the impacts of LULC change for the hydrology of UBNRB the study area.

## 1. Introduction

The Abay (Upper Blue Nile) River in Ethiopia contributes more than 60 % of the water resources ~~in~~ of the Nile ~~R~~iver (McCartney et al., 2012). Hence, the Ethiopian government has ~~conducted~~~~carried out~~ a series of studies to tap this huge potential water resource ~~with intent~~~~aiming~~ to significantly increase ~~the number of~~ large ~~water -storage~~ reservoirs ~~for water storage~~ in the Upper Blue Nile River Basin (UBNRB), both for irrigation and hydropower development, ~~in order~~ to support national development and ~~to~~ reduce poverty (BCEOM, 1998). As a result, large-scale irrigation and hydropower projects ~~such as the Grand Ethiopian Renaissance Dam (GERD), which will be the largest dam in Africa after it is completed,~~ ~~has~~ ~~have~~ been planned and realized—along the main stem of ~~the~~ Blue Nile River ~~such as the Grand Ethiopian Renaissance Dam (GERD), the largest dam in Africa when it is completed.~~ However, its hydrology ~~exhibiting high seasonal flows,~~ is influenced by ~~large~~~~high~~ variations in climate, ~~and~~ altitude/topography, ~~and by~~ land use/cover (LULC) change ~~exhibiting highly seasonal flows.~~ ~~E~~Therefore, effective planning, management, and regulation of water resource developments ~~is~~ ~~are~~ ~~therefore~~ required to ~~avert~~~~prevent the~~ conflicts between the competing water users —particularly ~~with the~~ downstream countries ~~such as of~~ Sudan and Egypt. ~~Establishing careful water resource management can mitigate p~~Potential conflicts ~~can be mitigat~~~~reduced~~ and ~~maximize~~ benefits ~~maximized if careful management of water resource is established.~~

~~Q~~~~This can be achieved only by~~ understanding the hydrological processes and sources impacting water quantity, such as LULC ~~change~~ and climate change, ~~can achieve this~~ as they are the key driving forces that can modify the ~~watershed's~~ hydrology and water availability~~ity of the watershed~~ (Oki and Kanae, 2006; Woldesenbet *et al.*, 2017b; Yin *et al.*, 2017a). LULC change can modify the rainfall path into ~~run off~~~~runoff~~ by altering critical water balance components, such as surface ~~run off~~~~runoff~~, groundwater recharge, infiltration, interception, and evaporation (Marhaento et al., 2017; Woldesenbet et al., 2017b). The UBNRB experiences significant spatial and temporal climate variability (McCartney et al. 2012). ~~L~~ess than 500 mm ~~yr<sup>-1</sup>~~ of precipitation falls ~~annually~~ near the Sudanese border ~~whereas~~~~to~~ more than 2,000 mm ~~falls annually~~~~yr<sup>-1</sup>~~ in some ~~ar~~~~plae~~~~as of~~~~in~~ the southern basin (Awulachew et al., 2009). Potential evapotranspiration (ET) also varies considerably and ~~is~~ ~~strong~~~~highly~~ correlated with altitude. ~~It exceeds~~ ~~varies from more than~~ 2,200 mm ~~yr<sup>-1</sup>~~ ~~annually~~ near the Sudanese border ~~to~~~~from~~ ~~between~~ ~~about~~ ~~approximately~~ 1,300 mm ~~and~~ ~~to~~ 1,700 mm ~~annually~~~~yr<sup>-1</sup>~~ in the Ethiopian highlands (McCartney et al., 2012). ~~T~~As a result of the precipitation and ET cycles ~~cause extreme seasonal and inter-annual variability,~~ ~~to strongly characterize~~ stream flow ~~is highly characterized by extreme seasonal and inter-annual variability.~~

A literature review shows that ~~there are~~ few sub-basin- ~~or~~ ~~and~~ basin-level studies ~~are conducted~~~~carried out~~ in the UBNRB. ~~M~~with most of the studies ~~were~~ ~~focus~~~~ed~~~~ing~~ on trend analysis of precipitation and streamflow. ~~Considering precipitation,~~ ~~most studies,~~ ~~for example,~~ ~~e.g.~~ ~~those by~~ (Bewket and Sterk, 2005; Cheung *et al.*, 2008; Conway, 2000; Gebremicael *et al.*, 2013; Melesse *et al.*, 2009; Rientjes *et al.*, 2011; Seleshi and Zanke, 2004; Teferi *et al.*, 2013; Tekleab *et al.*, 2014; Tesemma *et al.*, 2010), reported no significant trend in annual and seasonal precipitation totals within the Lake Tana ~~sub-basin~~~~sub-~~

basin, ~~w~~Whereas ~~he~~ Mengistu et al. (2014) reported statistically non-significant increasing trends ~~in~~at annual and seasonal rainfall series, ~~except~~ ~~for~~ a short rainy season (Belg-) from February to May.

5 ~~For the streamflow of the UBNRB,~~ Gebremicael *et al.* (2013) reported statistically significant increasing long-term mean annual streamflow at the El Diem gauging station ~~for the UBNRB's streamflow~~. However, (Tesemma *et al.*, 2010) reported no statistically significant trend for ~~the~~ long-term annual streamflow at ~~the~~ ElDiem gauging station, but ~~did report~~ a significantly increasing trend at ~~the~~ Bahirdar and Kessie stations. At the ~~sub-basin~~sub-basin scale, Rientjes et al. (2011) reported ~~a decreasing trend~~ for the low ~~streamflows~~ of Gilgel Abay ~~sub-basin~~sub-basin (Lake Tana catchment, the Blue Nile headwaters) during the ~~period~~ (1973–2005 ~~period~~), specifically by 18.1 % and 66.6 % in the periods 1982–2000 and 10 2001–2005, respectively. However, ~~for the same periods,~~ the high ~~streamflows~~ ~~for the same periods~~ show an increase by 7.6 % ~~and~~ 46.6 % due to LULC change and seasonal ~~rainfall~~ variability ~~of rainfall~~.

Although, substantial progress has been made in assessing the impacts of LULC and climate changes ~~on the UBNRB's hydrology~~ of the UBNRB, only ~~a~~ few studies have ~~endeavor~~attempted to assess the attribution of changes in the water 15 balance to LULC ~~change~~ and climate change. Woldesenbet et al. (2017b), used an integrated approach comprising SWAT hydrological modeling and partial least squares regression (PLSR) to quantify the contributions of changes in individual LULC classes to changes in hydrological components in ~~the two watersheds namely:~~ Lake Tana and Beles ~~sub-basin~~subbasins' ~~watersheds~~. Woldesenbet *et al.* (2017b) reported that expansion of cultivation land ~~area~~ and decline in woody shrub/woodland appear to be major environmental stressors affecting local water resources such as increasing surface 20 ~~run-off~~runoff and decreasing of ground water contribution in both watersheds; ~~however,~~but the impacts of climate change ~~is~~ missing ~~were not considered~~. ~~Nonetheless,~~However, proper water ~~resource~~ management requires an in-depth understanding of ~~n~~ the aggregated and disaggregated effects of LULC and climate changes on streamflow and water balance components as the interaction between LULC, ~~the~~ climate characteristics, and the underlying hydrological processes are complex and 25 ~~dynamic~~ (Yin *et al.*, 2017a). ~~τ~~

Therefore, ~~the objectives of this study's objectives~~ are ~~as follows~~therefore to (i) assess the long-term trend of rainfall and streamflow (ii) ~~analyze~~ ~~the~~ LULC change, ~~and~~ (iii) examining ~~the~~ streamflow responses to ~~the~~ combined and isolated effects of LULC and climate changes in the UBNRB. This ~~is can be doable~~ne ~~by using a~~ combining ~~ed~~ analysis of statistical trend test, change detection of LULC derived from satellite remote sensing, ~~and~~ hydrological modelling during the ~~period~~ 30 1971–2010 ~~period~~.

## 2. Study area

The UBNRB is located in ~~the northwestern~~ of Ethiopia, with ~~its an approximate~~ catchment area ~~is of about~~ 172,760 km<sup>2</sup>. ~~Topography of the basin is typically characterized by h~~Highlands, hills, valleys, and occasional rock peaks with elevations ~~that ranging~~ from 500 m.a.s.l to above 4000 m.a.s.l. ~~(Figure 1)~~ typically characterize the basin's topography (Figure 1). According to BCEOM (1998), ~~two thirds~~ ~~the larger portion~~ of the basin ~~(2/3)~~ lies in ~~the Ethiopia's~~ highlands ~~of Ethiopia~~ with annual rainfall ranging from 800 mm to 2,200 mm. A central and south-eastern area is ~~characterised~~ ~~characterized~~ by relatively high rainfall (1400- ~~mm to~~ 2200 mm) ~~although~~ ~~nd~~ less than 1200 mm rainfall ~~fell~~ ~~occurred~~ in most of the eastern and north-~~western~~ parts of the basin. Mekonnen and Disse (2018) showed that the UBNRB has a mean areal annual rainfall of 1452 mm, and ~~a~~ mean annual minimum and maximum temperatures of 11.4 °C and 24.7 °C respectively.

~~The climate of the study area is characterized by~~ tropical climate ~~characterizes the study area, which is and~~ dominated by its high altitude. ~~M~~ ~~The climate is also governed by the~~ movement of the Inter-Tropical Convergent Zone (ITCZ) ~~also governs the climate~~ (Conway, 2000; Mohamed et al., 2005). NMA (2013) classified the climate into three seasons in Ethiopia. The main rainy season (Kiremt) ~~lasts~~ generally ~~lasts~~ from June to September during which south-west winds bring rains from the Atlantic Ocean. ~~About~~ ~~Some~~ 70-90 % of ~~the~~ total rainfall occurs during this season. ~~—~~ A dry season (Bega) lasts from October to January and the short rainy season (Belg) lasts from February to May. According to BCEOM (1998), the average annual discharge is estimated about 49.4 Billion Cubic Meter (BCM), with the low-~~flow~~ month (April) equivalent to less than 2.5 % of that of the high-~~flow~~ month (August), at the Ethio-Sudan border (El Diem). The analysis of this study revealed that the long-term (1971-2010) mean annual volume of flow at El Diem is 50.7 BCM, with the low flow (dry season) contributing 21.1 % and the short rainy season accounting for about 6.2 %, ~~while~~ ~~M~~ ~~whereas~~ most flow occurred during the rainy season, contributing about 73 % (~~Table 1~~ ~~Table 1~~ ~~Table 1~~ ~~Table 1~~ ~~Table 1~~ ~~Table 1~~ ~~Table 1~~ ~~Table 1~~ ~~Table 1~~). ~~The land cover of the basin's~~ ~~land cover~~ essentially follows the divide between highland and lowland. ~~The highlands are predominantly covered by~~ ~~Predominantly~~ farmlands (about 90 %), bush, and shrubs ~~cover the highlands~~. The lowlands, in contrast, are still largely untouched by development, ~~As~~ a result, woodlands, bush, and shrub lands are the dominant forms of land cover (BCEOM, 1998).

## 3. Input data sources

In this study, non-parametric Mann-Kendal (MK) (Kendall, 1975; Mann, 1945) statistics and ~~the~~ Soil and Water Assessment Tool (SWAT), developed by the Agricultural Research Service of the United States Department of Agriculture (USDA-ARS) (Arnold et al., 1998), are used for statistical trend analysis and water-~~balance~~ modelling respectively. ~~T~~ ~~Details about the methods' details~~ are described under section 4. The input datasets used for ~~the~~ SWAT model can be ~~categorised~~ ~~categorized~~ into ~~those containing~~ weather-~~and~~ ~~streamflow~~-~~data~~, and spatially distributed datasets.

### 3.1 Weather and streamflow data

The daily weather variables used in this study for trend analysis and for driving the water<sub>-</sub>balance model are precipitation, minimum air temperature (Tmin), maximum air temperature (Tmax), relative humidity (RH), hours of sunshine (SH)<sub>2</sub> and wind speed (WS). ~~Thiese~~ weather data w<sub>a</sub>e<sub>r</sub>s<sub>e</sub> obtained from the Ethiopian National Meteorological S<sub>e</sub>r<sub>v</sub>i<sub>c</sub>e Agency (ENMSA) for the ~~period~~ 1971–2010 period. The daily streamflow data for over 25 gauging stations was collected from the Federal Ministry of Water, Irrigation and Electricity of Ethiopia for the ~~period~~ 1971–2010 period. After intensive and rigorous analyses of the weather data, a considerable amount of time -series data w<sub>a</sub>e<sub>r</sub>s<sub>e</sub> found to be missed in most of the stations (see Table ~~s01S01~~). due to The occurrences of civil war, and defective and outdated devices were the main causes for the missing data records. As a result, the available data constrained us to focus on only the ~~for~~ 15 stations (Figure 1) in which rainfall data are ~~is~~ relatively more complete. All 15 stations were used for trend analysis while whereas the 10 stations which having complete climate variables, such as Tmax, Tmin, RH, WS<sub>2</sub> and SH<sub>2</sub> were used as input for the SWAT model Figure 1.

We have used spatial interpolation techniques, such as the inverse distance weighting method (IDWM)<sub>2</sub> and linear regression techniques (LR) to fill the gaps. ~~Similar approaches or methods were applied by~~ Uhlenbrook et al. (2010) applied similar approaches or methods to ~~for~~ the Gilgel Abbay sub-basin ~~sub-basin~~, which is the UBNRB's headwater ~~of~~ UBNRB. The selection and number of adjacent stations are critically important for the accuracy of the estimated results. As mentioned by Woldesenbet et al. (2017a), different authors used different criteria to select neighboring stations. Because of ~~study area's~~ low station density ~~of the study area, for most stations,~~ a geographic distance of 100 km w<sub>a</sub>e<sub>r</sub>s<sub>e</sub> considered for most stations when ~~to~~ selecting neighbouring stations. If no station is located within 100 km of the target station, then the search distance is increased until at least ~~the minimum of~~ one suitable station is reached. After the neighbouring stations were selected, the two methods (IDWM and LR) were tested to fill in missing datasets. ~~The performance of the~~ candidate methods' performances were ~~as~~ evaluated using the statistical metrics such as root mean square error (RMSE), mean absolute error (MAE), correlation coefficient ( $R^2$ )<sub>2</sub> and percent bias (% bias) between observed and estimated values for the target stations. Equally weighted statistical metrics is are applied to compare the performances of selected methods at target stations and ~~to~~ establish ranking. A score was assigned to each candidate method according to the individual metrics; For example, e.g. the candidate ~~one~~ achieving the smallest RMSE and MAE, or % bias has got score 1, and so on. The final score is obtained by summing up the score pertaining ~~ed~~ to each candidate approaches at each stations. The method which with the has smallest score is the best. ~~The best method is the one having the smallest score.~~ The monthly, seasonal, and annual weather data w<sub>a</sub>s ~~ere~~ aggregated from the daily time<sub>-</sub>series data after filling the gaps. While filling in the missing data, uncertainty is expected due to ~~the~~ low station density, poor ~~co~~re~~lations~~ correlations, and the considerable number of missing records. Similar techniques and approaches were used for the analysis and filling in of the missing ed records of streamflow data records.

### 3.2 Spatial Data:

~~S~~patially distributed data ~~for required for the~~ SWAT model includes tabular and spatial soil data, tabular and spatial land use /cover information, and elevation data.— A Shuttle Radar Topographic Mission Digital Elevation Model (SRTM DEM) of 90 ~~metres—meters~~ resolution from the Consultative Group on International Agricultural Research- Consortium for Spatial Information (CGIAR-CSI; <http://srtm.csi.cgiar.org/SELECTION/inputCoord.asp>) was used to delineate the watershed and to ~~analyse—analyze~~ the ~~drainage patterns of the~~ land surface terrain's drainage patterns. Sub-basin parameters such as slope gradient, slope length of the terrain, and the stream network characteristics such as channel slope, length, and width were derived from the DEM.

The soil map developed by the Food and Agriculture Organization of the United Nations (FAO-UNESCO) at a scale of 1:5,000,000 ~~and~~ downloaded from (<http://www.fao.org/soils-portal/soil-survey/soil-maps-and-databases/faunesco-soil-map-of-the-world/en/>) was used for the SWAT model. ~~S~~The soil information such as soil textural and physiochemical properties needed for the SWAT model was extracted from Harmonized World Soil Database v1.2, a database that combines existing regional and national soil information (<http://www.fao.org/soils-portal/soil-survey/soil-maps-and-databases/harmonized-world-soil-databasev12/en/>) ~~in combination~~ with information provided by the FAO-UNESCO soil map (Polanco et al., 2017).

The LULC maps, representing one of the most important driving factors ~~to~~ affecting surface ~~run-off~~ runoff and evapotranspiration in a basin, were produced from satellite-remote-sensing Landsat images for 1973, 1985, 1995, and 2010 at a scale of 30 m x 30 m resolution.— Detailed image processing and classification approaches ~~are~~ described under section 4.2.

## 4. Methodology

### 4.1 Trend Analysis

The non-parametric Mann-Kendal (MK) (Kendall, 1975; Mann, 1945) statistics is chosen to detect trends for precipitation and streamflow time-series data as it is widely used for effective water resource planning, design, and management (Yue and Wang, 2004). Its advantage over ~~the~~ parametric tests, such as t-test, is that the MK test is ~~—~~ more suitable for non-normally distributed, and missing data, which ~~is are are~~ frequently encountered in hydrological time-series (Yue *et al.*, 2004). However, the existence of ~~—~~ positive serial correlation in a time-series data affects the ~~result of~~ MK-test result. If serial correlation exists in a time-series data, the MK test rejects the null hypothesis of no trend detection more often than specified by the significance level (von Storch, 1995).

~~In order to limit the influence of serial correlation on the MK test, pre-whitening was proposed by~~ von Storch (1995) proposed prewhitening to limit the influence of serial correlation on the MK test. ~~And also,~~ the Effective or Equivalent Sample Size (ESS) method developed by Hamed and Rao (1998) has also been proposed to modify the variance. However, the study by (Yue *et al.*, 2002) reported that von Storch's pre-whitening is effective only when no trend exists and the ~~rejection rate of the~~ ESS approach's rejection rate after modifying the variance is much higher than the actual (Yue *et al.*, 2004). ~~Then,~~ Yue *et al.* (2002) then proposed trend-free pre-whitening (TFPW) prior to applying the MK trend test in order to minimize its limitation. This study therefore employed TFPW to remove the serial correlation and to detect a trend in a time-series data series with significant serial correlation. Further details can be found in (Yue *et al.*, 2002). All the trend results in this paper have been evaluated at the 5 % level of significance to ensure ~~an~~ effective exploration of the trend characteristics within the study area.

### Change point test

The Pettitt test is used to identify whether or not there is a point change or jump in the data series (Pettitt, 1979). This method detects one unknown change point by considering a sequence of random variables,  $X_1, X_2, \dots, X_T$  that may have a change point at  $N$  if  $X_t$  for  $t = 1, 2, \dots, N$  has a common distribution function,  $F_1(x)$  ~~and a~~ ~~nd~~  $X_t$  for  $t = N + 1, \dots, T$  has a common distribution function,  $F_2(x)$ , and  $F_1(x) \neq F_2(x)$ .

### Sen's slope estimator

The trend magnitude is estimated using a non-parametric median-based slope estimator proposed by (Sen, 1968) as it is not greatly affected by gross data errors or outliers, and ~~it~~ can be computed when data ~~is~~ ~~are~~ missing. The slope estimation is given by:

$$\beta = \text{Median} \left[ \frac{X_j - X_k}{j - k} \right] \text{ for all } k < j, \text{ } \underline{\hspace{10em}} \text{ (---1)}$$

~~W~~here  $1 < k < j < n$ , and  $\beta$  is considered as the median of all possible combinations of pairs for the whole data set. A positive value of  $\beta$  indicates an upward (increasing) trend and a negative value indicates a downward (decreasing) trend in the time series. All MK trend tests, Pettitt change-point detections, and Sen's slope analyses were conducted using the XLSTAT add-ins tool from excel ([www.xlstat.com](http://www.xlstat.com)).

## 4.2- Remote sensing land use/cover map

### 4.2.1. Landsat image acquisition

Landsat images ~~from~~ ~~of~~ the years 1973, 1985, 1995, and 2010 were accessed free-of-charge from the US Geological Survey (USGS) Center for Earth Resources Observation and Science (EROS) via <http://glovis.usgs.gov>. The Landsat image scenes

were selected based on the criteria of acquisition period, availability, and ~~percentage~~ of cloud cover. ~~According to the recommendation of~~ (Hayes and Sader, 2001), recommend acquiring images ~~needed to be acquired from~~ the same acquisition period, ~~in order~~ to reduce scene-to-scene variation caused by ~~due to~~ sun angle, soil moisture, atmospheric condition, and vegetation ~~phenology~~ differences. ~~Hence, cloud free~~ images were hence collected for the dry months of January to May. However, as the basin covers a large area, each ~~period of the~~ LULC map's periods comprised ~~of~~ 16 Landsat scenes; ~~A therefore, it was difficult to a~~ accessing all the scenes during ~~in~~ a dry season ~~in~~ of a single year was therefore difficult. Hence, images were acquired  $\pm 1$  year for each time period and ~~also~~ some images were also acquired in the months of November and December. ~~For 1973, for example, 16~~ Landsat MSS image scenes were acquired in 1973 (10 images in ~~the month of~~ January, 4 images in ~~the month of~~ December ~~December~~ and 2 images in ~~the month of~~ November) ~~in 1973~~ ( $\pm 1$  years) and merged to arrive at one LULC representation for selected years. Please see supplement Table s02 for the details of Landsat images.

#### 4.2.2 Pre-processing and processing images

Several standard pre-processing methods including geometric and radiometric correction were implemented to prepare the LULC maps from Landsat images. ~~Al~~ Even though ~~there are~~ many different classification methods exist, supervised and unsupervised classifications are the two most widely used methods for landcover classification from remote-sensing images. Hence, in this study, a hybrid supervised/unsupervised classification approach was adopted ~~carried out~~ to classify the images ~~from~~ of 2010 (Landsat TM). ~~Firstly,~~ Iterative Self-Organizing Data Analysis (ISODATA) clustering was first performed to determine the image's spectral classes or land cover classes ~~of the image~~. ~~Secondly,~~ P polygons for all of the training samples based on the identified LULC classes were then digitized using ground truth data, ~~T and then~~ the samples for each land cover type were then aggregated. Finally, a supervised classification was performed using a maximum likelihood algorithm ~~in order~~ to extract four LULC classes.

A total of 488 Ground Control Points (GCPs) regarding landcover types and their spatial locations were collected from field observation in March and April, 2017 using a Global Positioning System (GPS). ~~Reference data (GCPs) was~~ ere collected and taken from areas where there had not been any significant landcover change between 2017 and 2010. These areas were identified by interviewing local elderly people, and supplemented ~~by~~ using high resolution Google Earth Images and the first author's ~~priori~~ knowledge of the first author. As many as 288 points were used for accuracy assessment and 200 points were used for developing training sites to generate a signature for each land-cover type. The ~~accuracy of the~~ classifications' accuracy was assessed by computing the error matrix (also known as the confusion matrix), ~~which that~~ compares the classification result with ground truth information as suggested by DeFries and Chan (2000). A confusion matrix lists the values for the reference data's known cover types ~~of the reference data~~ in the columns and for the classified data in the rows (Banko, 1998) as shown in Table 5. From the confusion matrix, a statistical metrics of overall accuracy, producers' accuracy

and users' accuracy are used. Another discrete multivariate technique ~~of-useful-~~ in accuracy assessment is called KAPPA (Congalton, 1991). The statistical metrics ~~s~~ for KAPPA analysis is ~~the~~ Kappa coefficient, which is another measure of the proportion of agreement or accuracy. The Kappa coefficient is computed as

$$K = \frac{N \sum_{i=1}^r x_{ii} \sum_{j=1}^r (x_{i+} * x_{+j})}{N^2 - \sum_{i=1}^r (x_{i+} * x_{+i})} \quad (2)$$

where r is the number of rows in the matrix,  $x_{ii}$  is the number of observations in row i and column i,  $x_{i+}$  and  $x_{+i}$  are the marginal totals of row i and column i, respectively, ~~and~~ N is the total number of observations.

Once the landcover classification of the year 2010 Landsat image ~~had been~~ completed and its accuracy ~~is~~ checked, the NDVI differencing technique (Mancino *et al.*, 2014) was applied to classify the images ~~from~~ 1973, 1985, and 1995. This technique was chosen to increase the accuracy of classification as it is hard to find an accurately classified digital or analog ~~ue~~ LULC map of the study area during ~~the period of~~ 1973, 1985, and 1995. ~~T~~ ~~And also,~~ the information obtained from the elders ~~is~~ ~~are~~ also more subjective and its reliability is questionable when there is considerable time gap. We first calculated the NDVI from the Landsat MSS (1973) and three pre-processed Landsat TM images (1985, 1995, ~~and~~ 2010) following the general normalized difference between band TM4 and band TM3 images ~~-(eqn. 3)~~. The resulting successive NDVI images were subtracted each other to assess the  $\Delta$ NDVI image with positive (vegetation increase), negative (vegetation cleared) and no change ~~at~~ a 30- ~~m~~ x 30 m pixel resolution (eqs. 4-6). The Landsat MSS 60- ~~m~~ x 60- ~~m~~ pixel-size data sets were resampled to a 30 m x 30 m pixel size using the ~~“nearest neighbour”~~ technique ~~in order~~ to have similar pixel sizes for the different images without altering the ~~image data's~~ original pixel values ~~of the image data~~.

$$NDVI = \frac{(TM4-TM3)}{(TM4+TM3)} \text{ or } \frac{(MSS_3-MSS_2)}{(MSS_3+MSS_2)} \quad (3)$$

$$\Delta NDVI_{1995/2010} = NDVI_{1995} - NDVI_{2010} \quad (4)$$

$$\Delta NDVI_{1985/1995} = NDVI_{1985} - NDVI_{1995} \quad (5)$$

$$\Delta NDVI_{1973/1985} = NDVI_{1973} - NDVI_{1985} \quad (6)$$

The  $\Delta$ NDVI image was then reclassified using a threshold value calculated as  $\mu \pm n*\sigma$ ; where  $\mu$  represents the  $\Delta$ NDVI pixels value mean, and  $\sigma$  the standard deviation. The threshold identifies three ranges in the normal distribution: (a) the left tail ( $\Delta NDVI < \mu - n*\sigma$ ); (b) the right tail ( $\Delta NDVI > \mu + n*\sigma$ ); and (c) the central region of the normal distribution ( $\mu - n*\sigma < \Delta NDVI < \mu + n*\sigma$ ). Pixels within the two tails of the distribution are characterized by significant landcover changes, ~~while~~ ~~whereas~~ pixels in the central region represent no change. To be more conservative, ~~n = 1~~ was selected for this study to

narrow the threshold ranges ~~of the threshold~~ for reliable classification. The standard deviation ( $\sigma$ ) is one of the most widely applied threshold identification approaches for different natural environments based on different remotely sensed imagery (Hu *et al.*, 2004; Jensen, 1996; Lu *et al.*, 2004; Mancino *et al.*, 2014; Singh, 1989) as cited by Mancino *et al.* (2014).

5  $\Delta$ NDVI pixel values (2010–1995) in the central region of the normal distribution ( $\mu - n \cdot \sigma < \Delta$ NDVI  $< \mu + n \cdot \sigma$ ) represent an absence of landcover change between two different periods (i.e., 1995 and 2010); therefore, pixels ~~from~~ 1995 corresponding to no landcover change can be classified as similar to the 2010 landcover classes. Pixels with significant NDVI change are again classified using supervised classification, taking signatures from the already classified, no-change pixels. Likewise, ~~landcover classification of~~ 1985 and 1973 landcover images ~~were as performed~~ classified based on the classified images of 1995 and 1985 respectively. Finally, after classifying the raw ~~images of~~ Landsat images into different landcover classes, change detection, which requires the comparison of independently produced classified images (Singh, 1989), was performed by the post-classification method. The post-classification change-detection comparison was conducted to determine changes in LULC between two independently classified maps from images of two different dates. Although this technique has some limitations, it is the most common approach ~~because~~ it does not require data normalization between two dates (Singh, 1989). This is because data from two dates are separately classified, thereby minimizing the problem of normalizing for atmospheric and sensor differences between two dates.

### 4.3 SWAT hydrological model

The Soil and Water Assessment Tool (SWAT) is ~~an~~ an open-source code, semi-distributed model with a large and growing number of model applications in a variety of studies ranging from catchment to continental scales (Allen *et al.*, 1998; Arnold *et al.*, 2012; Neitsch *et al.*, 2002). It enables ~~to evaluates~~ the impact of LULC change and climate change on water resources to be evaluated in a basin with varying soil, land use, and management practices over a set period of time (Arnold *et al.*, 2012).

25 In SWAT, the watershed is divided into multiple sub-basins, which are further subdivided into hydrological response units (HRUs) consisting of homogeneous land-use management, slope, and soil characteristics (Arnold *et al.*, 2012; Arnold *et al.*, 1998). HRUs are the smallest units of the watershed in which relevant hydrologic components such as evapo-transpiration, surface ~~run off~~ runoff and peak rate of ~~run off~~ runoff, groundwater flow, and sediment yield can be estimated. Water balance is the driving force behind all of the processes in the SWAT calculated using eq. 7.

$$SW_t = SW_o + \sum_{l=1}^t (R_{\text{day}} - Q_{\text{surf}} - E_a - W_{\text{seep}} - Q_{\text{gw}}) \quad (7)$$

where  $SW_t$  is the final soil-water content (mm H<sub>2</sub>O),  $SW_o$  is the initial soil-water content on day  $i$  (mm H<sub>2</sub>O),  $t$  is the time (days),  $R_{day}$  is the amount of precipitation on day  $i$  (mm H<sub>2</sub>O),  $Q_{surf}$  is the amount of surface runoff on day  $i$  (mm H<sub>2</sub>O),  $E_a$  is the amount of evapo-transpiration on day  $i$  (mm H<sub>2</sub>O),  $W_{seep}$  is the amount of water entering the vadose zone from the soil profile on day  $i$  (mm H<sub>2</sub>O), and  $Q_{gw}$  is the amount of return flow on day  $i$  (mm H<sub>2</sub>O).

5

Runoff is calculated separately for each HRU and routed to obtain the total streamflow for the watershed using either the soil conservation service (SCS) curve number (CN) method (Mockus, 1964) or Green & Ampt infiltration method (GAIM) (Green and Ampt, 1911) Figure 2. However, spatial connectivity and interactions among HRUs are ignored. Instead, the cumulative output of each spatially discontinuous HRUs at the subwatershed outlet is directly routed to the channel (Pignotti et al., 2017). This lack of spatial connectivity among HRUs makes implementation and impact analysis of spatially-targeted management such as soil and water conservation structure difficult to incorporate into the model. To overcome this problem, efforts were made by different authors have made efforts to overcome this problem. For instance, a grid-based version of the SWAT model (Rathjens et al., 2015); or landscape simulation on a regularized grid (Rathjens and Oppelt, 2012). Moreover, (Arnold et al., 2010) and (Bosch et al., 2010) further modified SWAT so that it allows landscapes to be subdivided into catenas comprising of upland, hillslope, and floodplain units, and flow to be routed through these catenas. However, SWATgrid, developed to overcome this limitation, remains largely untested and computationally demanding (Rathjens et al., 2015).

10

15

Hence, the standard SWAT-CN method was chosen for this study because it is tested in many Ethiopian watersheds of Ethiopia such as (Gashaw et al., 2018; Gebremicael et al., 2013; Setegn et al., 2008; Woldesenbet et al., 2017b). Furthermore, and because of its ability to use daily input data (Arnold et al., 1998; Neitsch et al., 2011; Setegn et al., 2008) as compared to GAIM, which requires sub-daily precipitation as a model input, and that can be difficult to obtain in data-scarce regions like the UBNRB. This study focused on the effects of LULC change and climate change on the basin's water balance components of the basin, which includes the components of inflows, outflows, and the change in storage. Precipitation is the main inflow; whereas evapo-transpiration (Et), surface runoff (Qs), lateral flow (Ql), and base flow (Qb) are the outflows. SWAT has three storages; namely, soil moisture (SM), shallow aquifer (SA) and deep aquifer (DA). Water movement from the soil-moisture storage to the shallow aquifer is due to percolation, whereas, water movement from the shallow aquifer reverse upward to the soil-moisture storage is Revap. For a more detailed description of the SWAT model, reference is made to Neitsch et al. (2011).

20

25

30

The SWAT model setup and data preparation can be done using arcSWAT tools in the arcGIS environment, while whereas parameter sensitivity analysis, and model calibration and validation was performed using the SWAT-CUP (Calibration and Uncertainty Procedures) interface Sequential Uncertainty Fitting (SUFI-2) algorithm (Abbaspour, 2008). During model set up, the observed daily weather and streamflow data from the given period was divided in to three different periods; the

first to warm up the model, the second to calibrate ~~it, the model~~ and the third to validate ~~it, the model~~. The first step in SWAT is ~~to~~ determine ~~ation of~~ the most sensitive parameters for a given watershed using ~~the~~ global sensitivity analysis option (Arnold *et al.*, 2012). The second step is ~~to complete~~ the calibration process ~~making necessary adjusting adjustments for~~ the model's input parameters ~~necessary~~ to match model output with observed data; thereby reducing the prediction uncertainty.

5 Initial parameter estimates were taken from the default lower and upper bound values of the SWAT model database and from earlier studies in the basin ~~such as e.g.~~ (Gebremicael *et al.*, 2013). The final step, model validation, involves running a model using parameters that were determined during the calibration process; and comparing the predictions to independently observed data not used in the calibration.

10 In this study, both manual and automatic calibration strategies were applied to attain the minimum differences between observed and simulated streamflows in terms of surface flow, ~~and~~ peak and total flow following the steps recommended by Arnold *et al.* (2012). For the purpose of impact analysis, we divided the simulation periods ~~in of (1971–2010)~~ into four decadal periods, hereafter referred as the 1970s (1971–1980), 1980s (1981–1990), 1990s (1991–2000) and 2000s (2001–2010), as shown in Table 2. The model's performance for the streamflow was then evaluated using statistical methods

15 (Moriassi *et al.*, 2007) such as the Nash–Sutcliffe coefficient of efficiency (NSE), the coefficient of determination ( $R^2$ ) and the relative volume error (RVE %), which are shown by eqs. 8–10. Furthermore, graphical comparisons of the simulated and observed data, as well as water balance checks, were used to evaluate the model's performance.

$$R^2 = \frac{[\sum(Q_{m,i} - \bar{Q}_m)(Q_{s,i} - \bar{Q}_s)]^2}{\sum(Q_{m,i} - \bar{Q}_m)^2 \sum Q_{s,i} - \bar{Q}_s^2} \quad (8)$$

$$NSE = 1 - \frac{\sum(Q_{m,i} - Q_{s,i})^2}{(\sum(Q_{m,i} - \bar{Q}_m))^2} \quad (9)$$

20  $RVE (\%) = 100 * \frac{\sum_{i=1}^n (Q_m - Q_s)_i}{\sum_{i=1}^n Q_{m,i}}$  (10)

where  $Q_{m,i}$  is the measured streamflow in  $m^3 s^{-1}$ ,  $\bar{Q}_m$  ~~are~~ is the mean values of the measured streamflow ( $m^3 s^{-1}$ ),  $Q_{s,i}$  is the simulated streamflow in  $m^3 s^{-1}$ , and  $\bar{Q}_s$  ~~are~~ is the mean values of simulated data in  $m^3 s^{-1}$ .

#### 4.4 SWAT simulations

25 ~~Three different approaches were taken applied~~ In order to for assessing the individual and combined effects of LULC ~~change~~ and climate change on streamflow and water balance components, ~~three different approaches were applied~~. The first approach is to assess the response of streamflow to combined LULC ~~change~~ and climate change. We divided the analysis period, ~~(1971–2010)~~ into four equal periods (four decades). ~~These are~~ periods when ~~land use changes are expected to change~~ the hydrological regime within a catchment ~~is expected to be changed due to land use changes~~ (Marhaento *et al.*,

2017; Yin *et al.*, 2017b). The first period, the 1970s, was regarded as the baseline period. ~~T~~and the other periods, the 1980s, 1990s, and 2000s, were regarded as altered periods. LULC maps of 1973, 1985, 1995, and 2010 were used to represent ~~the~~ LULC patterns ~~of~~ during the ~~period~~-1970s-, 1980s, 1990s, and 2000s respectively. To analyze the response of streamflow and water balance components caused by the combined effects of LULC and climate change during decadal time periods, the SWAT model was separately calibrated and validated for each decades using the respective LULC map and weather data (Table 2). The DEM and soil data sets remained unchanged. The differences between the simulation result of the baseline and altered periods represent the combined effects of LULC and climate changes on streamflow and water balance components.

The second approach included simulations to attribute ~~only effects from~~ LULC changes alone. It aimed to investigate whether LULC change is the main driver for changes in water balance components. To identify the hydrological impacts caused solely by LULC ~~only~~, "A fixing-changing" method was used (Marhaento *et al.*, 2017; Woldeesenbet *et al.*, 2017b; Yan *et al.*, 2013; Yin *et al.*, 2017a). The calibrated and validated SWAT model and its parameter settings in the baseline period ~~were~~ forced by weather data from ~~the~~-baseline period, 1973-1980, while changing only the LULC maps from 1985, 1995, and 2010, keeping the DEM and soil data constant as suggested by (Hassaballah *et al.*; Marhaento *et al.*, 2017; Woldeesenbet *et al.*, 2017b; Yin *et al.*, 2017a). We ran the calibrated SWAT model for the baseline period (1970s) four times changing only the LULC map ~~from~~ the years 1973, 1985, 1995, and 2010 and ~~remaining~~ the constant weather data set from the 1970s (Table 2). The third approach is similar to the second ~~approach~~ but the simulations are attributed only for climate changes. A model was run again four times, corresponding to the LULC periods using a unique LULC map of the year 1973 but altering the four different periods of weather data sets (1970s, 1980s, 1990s, and 2000s).

## 5. Results and discussions

### 5.1 Trend test

#### 5.1.1 Rainfall

The summary of the MK trend ~~-~~tests result for the rainfall recorded at the 15 selected stations located inside and around the UBNRB revealed a mixed trend (increasing, decreasing, and no change). For daily time series, the computed probability values (p-values) for seven stations was greater, although ~~while~~ for eight stations it was less, than the given significance level ( $\alpha = 5\%$ ). This means that no statistically significant trends existed in seven stations, but a monotonic trend ~~was~~ occurred in the remaining eight ~~stations~~. Positive trends developed ~~occurred~~ only at six ~~stations~~, four of ~~which~~ 4 stations were concentrated in the northern and central highlands (Bahirdar, Dangila, Debre Markos, and G/bet); The other two stations, (Assosa and Angergutten), are located in the south-western and southern lowlands (see Figure 1). The other two stations,

Alemketema and Nedjo ~~respectively, which are~~ located in the ~~EE~~East and ~~SS~~Southw-West of ~~the~~ UBNRB, ~~respectively showed~~ ~~They show~~ a decreasing trend. On monthly basis, the MK trend test result showed that no statistically significant trend existed in all 15 stations. On an annual time scale, MK trend test could not find any trend in 11 stations, ~~while although four stations~~ ~~the~~ (Alemketema, Debiremarkos, Gimijabet, and Shambu ~~stations~~) ~~did~~ exhibited a trend. The trend analysis result ~~for~~ of the annual rainfall time series ~~has a good~~ agrees ~~well~~ with a previous study by Gebremicael *et al.* (2013), who reported no significant ~~change of~~ annual rainfall ~~change at eight~~ ~~in~~ 8 out of ~~nine~~ 9 stations during the ~~period~~ 1973–2005 ~~period~~. Hence, it is interesting to note that the time scale of analysis is critical factor ~~to~~ ~~in~~ determining the given trends.

The basin-wide rainfall trend and change point analysis was again carried out ~~on~~at daily, monthly, seasonal, and annual time scales using ~~the~~ MK ~~test~~ and Pettitt tests ~~respectively, as~~ ~~respectively as~~ summarized in Table 3 and Figure 3. The MK ~~test~~ showed increasing trends for annual, monthly, and long-rainy-season rainfall series ~~whereas~~ ~~the~~ no trend for daily, short rainy, and dry-season rainfall series ~~appeared~~. The magnitude of trends for annual, monthly, and long-rainy-season rainfall series are not significant, as explained by the values of Sen's slope. However, the Pettitt test could not detect any jump point in basin-wide rainfall series except for daily time-series rainfall ([see Figure S01](#)).

Previous studies' ~~authors, such as~~ (Conway, 2000; Gebremicael *et al.*, 2013; Tesemma *et al.*, 2010), ~~conducted~~ ~~carried out~~ ~~the~~ trend analysis of ~~the~~ basin-wide rainfall ~~and~~ ~~such as~~ (Conway, 2000; Gebremicael *et al.*, 2013; Tesemma *et al.*, 2010), reported that no significant change ~~of~~ ~~in~~ annual and seasonal rainfall series ~~across~~ ~~over~~ the UBNRB ~~which contradicts with~~ ~~the result of this study~~. This disagreement could be due to the number of stations and their spatial distribution ~~across~~ ~~over~~ the basin, time period of the analysis, approach used to calculate basin-wide rainfall from gauging stations, and ~~data~~ sources ~~of~~ ~~data~~. Tesemma *et al.* (2010) ~~was~~ used monthly rainfall data downloaded from Global Historical Climatology Network (NOAA, 2009) (GHCN) data base and ~~the~~ 10-day rainfall data for the 10 selected stations obtained from the National Meteorological Service Agency of Ethiopia from 1963–2003. Conway (2000) ~~was~~ also constructed basin-wide annual rainfall ~~in the~~ of UBNRB for the ~~period~~ 1900–1998 ~~period~~ from the mean of 11 gauges. Furthermore, (Conway, 2000) employed simple linear regressions over time to detect trends in annual rainfall series without removing the serial autocorrelation effects. Gebremicael *et al.* (2013), also used only ~~9~~ ~~nine~~ stations from the ~~period~~ 1970–2005 ~~period~~. However, in this study, we used daily observed rainfall data from 15 stations collected from Ethiopian Meteorological Agency from 1971–2010. The stations are more or less evenly spatially distributed over ~~the~~ UBNRB. We applied a widely used spatial interpolation technique, ~~the~~ (Thiessen polygon method,) to calculate basin-wide rainfall series from station data.

### 5.1.2 Streamflow

The ~~result of~~ MK-~~test's~~ ~~result~~ for daily, monthly, annual, and seasonal (long and short rainy season and dry season) time-series streamflow showed a positive trend, and the ~~trend~~ magnitude ~~of which~~ is statistically significant, as ~~summarised~~

summarized in Table 3. Meanwhile, although the Pettitt test detects change point for daily, annual, and short-rainy-season streamflows, it cannot detect change point for monthly, long, and dry season streamflows (see Figure 3 and Figure S02). The change point detected by the Pettitt test for annual rainfall series is occurred in 1995 while-whereas for daily and dry seasons it is are respectively in 1985 and 1987. The result obtained from the MK test has a good-agrees wellment with the previous study conducted-carried-out by Gebremicael et al. (2013), which reported an increasing trend in the observed annual, short, and long rain seasons' streamflow at the El Diem gauging station, but disagrees with the result for-of dry-season streamflow. Furthermore, the increasing trend of long-rainy-season streamflow well-agrees well with—the result of Tesemma et al. (2010), but disagrees with the results of short rainy season and annual flows. (Tesemma *et al.*, 2010), reported that the short rainy season and the annual flows are constant for the -analysed-period-of-1964–2003 period analyzed. This-disagreement is likely attributable-ed to the difference in-of analysis period, as can be seen from Figure 3. The last seven years, -(2004–2010,) had relatively higher streamflow records.

Although, the results of MK test for the-annual and long-rainy-season rainfall and streamflow show an increasing trend for the last 40 years in the UBNRB, the magnitude of Sen's slope for streamflow is much great-larger than it is for-the-Sen's-slope of rainfall (Table 3). Moreover, for-the-short-rainy-season streamflow shows a statistically significant positive increaseing whereas-the rainfall shows no change. The mismatch of-trend-magnitude-between rainfall and streamflow trend magnitude could be associated with evapotranspiration and attributable-ed to the combined effect of LULC change and climate change, associated-with—evapotranspiration,—infiltration rate due to-by changing soil properties,—rainfall intensity, and extreme events.

## 5.2 LULC change analysis

According to the confusion-matrix report, overall accuracy of 80 %, producer's accuracy values for all classes ranged from 75.4 % to 100 %, user's accuracy values ranging-ed from 83.7 % to 91.7 % and the kappa coefficient (k) of 0.77 were attained for the 2010 classified image, as shown in Table 5. Monserud (1990) suggested a kappa value of -<40 % as poor, 40–55 % fair, 55–70 % good, 70–85 % very good, and >85 % as excellent. According to these ranges, the classification in this study has very good agreement with the validation data set and met the minimum accuracy requirements to be used for further-change detection and impact analysis.

The classified images of the basin (Figure 4) have shown different LULC proportions at four distinct-fferent time periods, as shown in Figure 5. In 1973, the UBNRB was dominated by-cultivated land dominantly covers (62.9 %) of UBNRB, followed by bushes &-and shrubs (18 %), forest (17.4 %), and water (1.74 %) dominated-the-UBNRB-in-1973. In 1985, the cultivated land area increased to (65.6 %), followed by bushes &-and shrubs (18.3 %), while forest decreased to (14.4 %), and water remained unchanged at (1.7 %). In 1995, cultivated land area further increased to (67.5 %), followed by bushes &-and shrubs (18.5 %), forest-Forest further decreased (to 12.2 %), and water remained unchanged (at 1.7 %). In 2010,

cultivated land decreased to (-63.9 %), bushes and shrubs increased to (18.8 %), forest increased to (15.6 %), and water remained unchanged at (-1.7 %). During the entire 1973–2010 period, cultivated land, along with bushes ~~& and~~ shrubs remained the major proportions ~~as~~ compared to the other LULC classes. The highest gain (2.7 %) and the largest loss (-3.6 %) in cultivated land occurred during the 1973–1985 and 1995–2010 periods respectively. The ~~larg~~ highest gain in bushes and shrubs was (0.3 %) from 1973 to 1985, ~~whereas~~ the ~~larg~~ highest gain in forest coverage (3.4 %) was recorded during the ~~period~~ 1995–2010 ~~period~~. Water coverage remained unchanged from 1973 to 2010.

Although, the image classification ~~has~~ enjoys very good accuracy, uncertainties could be expected for the following reasons. Firstly, as elsewhere in Ethiopia, LULCs change rapidly over ~~the land surface of the basin spaces~~, and image reflectance may be confusing due to the topography and variation in the image acquisition date. Landsat images were not all available for one particular year or one season; ~~thus~~ images ~~thus~~ came from a mix of years, and ~~from~~ a variety of seasons, ~~and~~ might harbor ~~ve~~ errors. Secondly, the workflow associated with LULC classification, ~~which~~ involves many steps and can be a source of uncertainty. The errors are observed in the classified LULC map as shown in Figure 4. ~~On the western side of the map~~ In Figure 4 (a) ~~on the western side of the map is~~ a rectangular section with forest ~~appears~~, ~~which~~ that completely disappears in 4(b). ~~In 4(b) there is a~~ rectangular forest cover ~~appears~~ in the northern part of the country ~~in 4(b)~~, which again disappears completely in 4(c). In 4(d), ~~a~~ forest cover with linear edges (North-South) appears on the ~~map's~~ eastern side ~~of the map~~. That being ~~recognised~~ recognized, ~~overall~~ the land ~~cover~~ mapping is reasonably accurate ~~overall~~, providing a good base for land ~~cover~~ estimation and for providing basic information for the ~~objective of~~ hydrological impact analysis.

The rate of expansion of cultivated land before 1995 was higher ~~than that~~ ~~as compared to~~ after 1995. Conversely, the area devoted to forest land decreased in ~~the~~ 1985 and 1995 from the ~~1973~~ baseline ~~1973~~. However, after 1995, the forest's ~~size~~ began to increase while the ~~amount of~~ cultivated land decreased. The increased forest coverage and the reduction in cultivated land over the period 1995 to 2010 showed that the environment was recovering from the devastating drought, and forest clearing for firewood and cultivation due to population growth has ~~been~~ minimized. This could be due to the afforestation program, ~~which~~ ~~me~~ initiated by the Ethiopian government ~~initiated~~, and ~~due~~ to the extensive soil and water conservation measures ~~carried out by the community~~. Since 1995, eucalyptus tree plantation expanded significantly across the country at homestead level for fire wood, construction material, ~~for producing~~ charcoal ~~production~~, and ~~for generating~~ income ~~generation~~ (Woldesenbet *et al.*, 2017b). ~~In~~ ~~to~~ summarize, ~~in the period 2010~~, forest coverage declined by 1.8 %, ~~while~~ ~~with increasing of~~ both bushes and shrubs, as well as cultivated land ~~increased~~ by 0.8 % and 1 % respectively ~~during the 2010 period~~ from the original 1973 level. This result agrees well with other studies (Gebremicael *et al.*, 2013; Rientjes *et al.*, 2011; Teferi *et al.*, 2013; Woldesenbet *et al.*, 2017b), who reported ~~the~~ a significant conversion of ~~natural~~ vegetation cover into agricultural land.

### 5.3 SWAT model calibration and validation

The SWAT model's most sensitive parameters for the SWAT model to simulate streamflow were identified using global sensitivity analysis of SWAT-CUP, and their optimized values were determined by the calibration process that recommended by Arnold *et al.* (2012) recommended. Parameters such as SCS curve number (CN2), base flow alpha factor (ALPHA\_BF), soil evaporation compensation factor (ESCO), threshold water depth in the shallow aquifer required for return flow to occur (GWQMN), groundwater "revap" coefficient (GW\_REVAP), and the available water capacity (SOL\_AWC) were found to be the most sensitive parameters for the flow predictions.

Figure 6 shows the calibration and the validation results for monthly streamflow hydrographs. These and this results revealed that the model well captured the monthly hydrographs well. This was again verified by the statistical performance measures of  $R^2$ , NSE, and RVE (%) statistical performance measures, as presented in Table 6, reverified this. For the calibration period, the values of  $R^2$ , NSE, and RVE (%) from the four model is ranged from 0.79 to 0.91, 0.74 to 0.91, and -3.4 % to -4 %. And for the validation period they it ranged from 0.84 to 0.94, 0.82 to 0.92, and -7.5 % to 7.4 % respectively. According to the rating of Moriasi *et al.* (2007), the performance of the SWAT model's performance over the UBNRB can be categorized as very good, although underestimation was observed in the base-flow simulation. The optimal parameter values of the four calibrated four model runs are shown in Table 7. A change was obtained for CN2 parameter values, which can be attributed to the catchment's response behaviour. For instance, an increase in the CN2 value in the 1980s and 1990s from 0.89-88 to 0.91 and 0.92 as compared to the 1970s respectively, indicate a reduction in forest coverage and expansion of cultivated land. In contrary, a decrease in CN2 value was attained during the period 1990s to 2000s from 0.92 to 0.9, attributed to the increase in forest coverage and reduction in cultivated land.

### 5.4 Combined Effects of combined LULC change and climate change on streamflow and water balance components

The simulation results of the four independent, decadal-time-scale-calibrated and validated SWAT model runs reflect indicate the combined effect of both LULC and climate change during the past last 40 years' time (Table 8). From the simulation result, mean annual streamflow increased by 16.9 % between the period 1970s and the 2000s. However, the rate of change is different in different decades. For example, it increased by 3.4 % and -9.9 % during the period-1980s and 1990s respectively from the baseline period-1970s period.

The ratio of mean annual streamflow to mean annual precipitation ( $Q_t/P$ ) increased from 19.4 % to 22.1 %, and actual evaporation to precipitation ( $E_a/P$ ) decreased from 61.1 % to 60.5 % from the 1970s to 2000s. Moreover, the ratio of surface runoff to streamflow ( $Q_s/Q_t$ ) has significantly increased significantly from 40.7 % in the 1970s to 50.1 % and 55.4 % in the 1980s and 1990s respectively, and decreased to 43.7 % in the 2000s. In contrast, the base flow to streamflow ratio ( $Q_b/Q_t$ ) has significantly decreased from 17.1 % in the 1970s to 10.3 % and 3.2 % respectively during the period

1980s and 1990s, but has increased to 20 % in the ~~period~~ 2000s. The result for surface runoff agrees with the previous study done by (Gebremicael *et al.*, 2013), but disagrees for baseflow. They reported surface runoff (Qs) contribution to the total river discharge has increased by 75%, while the baseflow (Qb) flow has decreased by 50% from the ~~period~~ 1970s to 2000s.

5 ~~This indicates that~~ In general, 1.8 % forest cover loss and 1 % increased cultivated land combined with 2.2 % increased rainfall from the 1970s to the 2000s led to a 16.9 % increase in simulated streamflow. The 1990s was the period ~~when during~~ which the ~~great~~ highest deforestation and expansion of cultivated land was reported; meanwhile, it is the time when the rainfall intensity and the number of rainfall events haves significantly increased compared to the 1970s and 1980s, as shown in Table 4. Hence, the increased mean annual streamflow could be ascribed to the combined effects of LULC and climate  
10 change. In the case of (Qs/Qt), the increasing pattern could be ascribed to ~~the~~ increasing ~~of~~ rainfall intensities and the expansion of cultivated land and ~~decreasing~~ diminution of forest coverage, which might adversely affect soil ~~water~~ storage, and decrease rainfall infiltration, thereby increasing water yield or streamflow. In contrast astary, the decreasing ~~of~~ (Qb/Qt) is ~~has~~ positively related ion to with the increasing ~~of~~ evapotranspiration linked to both LULC and climate factors (Table 8). This hypothesis can be explained with the change in CN2 parameter values obtained during ~~the~~ calibration of the four SWAT  
15 model runs.

The CN2 parameter value — which is a function of evapotranspiration derived from LULC, soil type, and slope —, increased in the 1980s and 1990s relative to the ~~from~~ 1970s, and could be associated with the expansion of cultivated land and shrinkage of forest land. The increasing ~~of~~ CN2 results ~~to~~ reflect generate more surface runoff and less baseflow being  
20 generated.

Another important ~~contributing~~ factor for contributing to ~~the~~ decreasing of surface ~~run-off~~ runoff and increasing ~~of~~ base flow ratio from 1990s to ~~in~~ the 2000s ~~from 1990s~~ could be the establishment of soil and water conservation (SWC) measures. According to Haregeweyn *et al.* (2015), various nationwide SWC initiatives ~~have been undertaken since the 1980s~~  
25 such as Food for Work (FFW) ~~(1973–2002)~~, Managing Environmental Resources to Enable Transition (MERET) to more sustainable livelihoods ~~(MERET, 2003–2015)~~, Productive Safety Net Programs (PSNP) ~~(PSNP, 2005–present)~~, Community Mobilization through free-labor days ~~(1998–present)~~, and the National Sustainable Land Management Project (SLMP);  
30 ~~2008–2018~~ have been undertaken since the 1980s. ~~The effectiveness of the initiatives were evaluated by~~ (Haregeweyn *et al.*, 2015) evaluated these initiatives' effectiveness and ~~come up with the conclusion~~ concluded that community labour mobilization seems to be the best approach. This ~~It~~ can reduce a mean seasonal surface ~~run-off~~ runoff by 40 %, with broad large spatial variability, ranging from 4 % in Andit Tid (northwest Ethiopia) to 62 % in Gununo (south Ethiopia).

## 5.5 Effects of an single isolated change in LULC change on streamflow and water balance components

To identify the hydrological impacts caused by LULC only, "A fixing-changing" method was used (Yan *et al.*, 2013) used "A fixing -changing" method to identify the hydrological impacts of LULC alone. The calibrated and validated SWAT model and its parameter settings in the baseline period was forced by weather data from the baseline ~~period~~ 1973–1980 period while changing only the LULC maps from 1985, 1995, and 2010, keeping the DEM and soil data constant as suggested by (Hassaballah *et al.*). The result— from— Figure 7~~Figure 7~~~~Figure 7~~~~Figure 7~~~~Figure 7~~~~Figure 7~~~~Figure 7~~~~Figure 7~~~~Figure 7~~ indicated that Qs/Qt ratio changed from 40.7 % to 41.2 %, 41.1 %<sub>s</sub> and 40.9 % respectively by using the LULC maps from 1973, 1985, 1995 and 2010 whereas the Qb/Qt ratio changed from 17.1 % to 16.8 %, 16.5 %<sub>s</sub> and 16.9 % respectively. The larg~~high~~est Qs/Qt ratio (41.9 %) and the small~~low~~est Qb/Qt ratio~~o~~ (16.5 %) were~~as~~ recorded with the 1995 LULC map ~~of 1995~~. This could be attributed to the 5.1 % reduction in forest coverage and 4.6 % increase in cultivated land with the 1995 LULC map relative~~as compared~~ to the 1973 LULC map.

On a basin scale; over a decadal time period, water gains mainly from precipitation; T~~and~~ the losses are mainly due to run-off~~runoff~~ and evapotranspiration (Oki *et al.*, 2006). With~~In~~ the fixing-changing approach, the change in streamflow attributable~~due~~ to LULC change was essentially the change in ~~the~~ evapotranspiration between the two periods, as the amount of precipitation was constant (1970s) and the change in ~~the~~ water storage during the two periods was similar (Yan *et al.*, 2013). A~~The~~ annual Ea losses from seasonal crops are smaller than those~~Ea losses~~ from forests, because~~as~~ seasonal crops only transpire during a relatively shorter time interval~~period~~ than perennial trees do~~transpire~~ (Yan *et al.*, 2013). As a result, the actual mean annual evapotranspiration (Ea) simulated— by the SWAT model was 871.6 mm at the baseline. It— decreased to 871.4 mm— and 871 mm in ~~the~~ 1985 and 1995 respectively and increased to 872.1 mm in ~~the~~ 2010. This could be due to simultaneous expansion of cultivated land and shrinkage in forest coverage in the 1985 and 1995 ~~LULC maps~~ ap of 1985 and 1995 ~~from~~ relative to the 1973 base line—~~1973~~. Furthermore, this deforestation may cause a reduction in canopy interception of the rainfall, decreases ~~the~~ soil infiltration by increasing raindrop impacts, and reduce ~~reducing~~ plant transpiration, which can significantly increase surface run-off~~runoff~~ and reducing base flow (Huang *et al.*, 2013). Here, the change of evapotranspiration change caused by the LULC change is minimal. A ~~as~~ a result, the change for surface runoff and baseflow is not significant.

## 5.6 Effects of single isolated climate change on streamflow and water balance components

The impacts of climate change are analysed ~~analyzed~~ by running the four models using a unique LULC map from~~of~~ 1973 with its model parameters while changing only the weather data sets from 1970s, 1980s, 1990s<sub>s</sub> and 2000s. The simulated water balance components shown in Figure 7~~Figure 7~~~~Figure 7~~~~Figure 7~~~~Figure 7~~~~Figure 7~~~~Figure 7~~~~Figure 7~~~~Figure 7~~ indicate that the Qs/Qt ratio increased from 40.7 % to 45.2 %, 45.6 %<sub>s</sub> and 46.2 % during the ~~period~~ 1970s, 1980s, 1990s and 2000s respectively, while; the Qb/Qt ratio changed from 17.1 % to 13.5 %, 14.9 %<sub>s</sub> and 12.7 % for the same simulation

periods. The decreasing ~~of the ratio of~~  $(Q_b/Q_t)$  ratio for the altered periods ~~as~~ compared to the baseline period could be attributed to ~~the increasing of~~ evapotranspiration increasing from 872 mm to 854 mm, 906 mm, and 884 mm respectively in 1970s, 1980s, 1990s, and 2000s, which can be linked to temperature and amount of rainfall. However, it is important to know the dominant rainfall-runoff process in of the study area to fully understand the effect of climate change on the water balance components.

Although, ~~there is no any detailed~~ research has been conducted ~~carried out~~ on the Blue Nile basin to investigate ~~about~~ the runoff-generation processes, Liu et al. (2008) investigated the rainfall-runoff processes at three small watersheds located inside and around Upper Blue Nile basin, namely, ~~Mayber, AnditTid, and Anjeni~~. Their analysis showed that, unlike in temperate watersheds, in monsoonal climates, a given rainfall volume at the onset of the monsoon produces a different ~~run-off~~ runoff volume than the same rainfall at the end of the monsoon. Liu et al. (2008) and Steenhuis et al. (2009) showed that the ratio of discharge to precipitation minus evapotranspiration,  $(Q/(P - ET))$ , increases with cumulative precipitation from the onset of monsoon. This suggests ing that saturation excess processes play an important role in watershed response.

Furthermore, the infiltration rates ~~measured in 2008 by that~~ Engda (2009) measured in 2008 were compared with rainfall intensities in the Maybar ~~and Andit Tid~~ watersheds located inside and around the UBNRB. In the Andit Tid watershed, which has an area of less than 500 ha, ~~the~~ measured infiltration rates at 10 locations were compared with rainfall intensities considered from the ~~period~~ 1986 ~~–~~ 2004 period. The analysis showed that only 7.8 % of rainfall intensities were found to be higher than the lowest soil infiltration rate of 2.5  $\text{cm hr}^{-1}$ . ~~A similar analysis was performed by~~ Derib (2005) performed a similar analysis in the Maybar watershed (with a catchment area of 113 ha). The infiltration rates measured from 16 measurements ~~were~~ ranged from 19 mm h<sup>-1</sup> to 600  $\text{mm hr}^{-1}$  with a ~~n average value of~~ 24  $\text{cm hr}^{-1}$  average and ~~the median was~~ 18  $\text{cm hr}^{-1}$  median whereas ~~the~~ average daily rainfall intensity from 1996 to 2004 was 8.5  $\text{mm hr}^{-1}$ . Hence, ~~from these infiltration measurements,~~ he suggested from these infiltration measurements that infiltration excess ~~run-off~~ runoff is not a common feature in these watersheds.

From the above discussion points, it is to be noted that surface runoff could increase with ~~the increasing of~~ total rainfall amount regardless of ~~rainfall~~ intensity. However, ~~in this study,~~ the mean annual rainfall amount in this study was decreasing from the 1970s to the 1980s (1428 mm and 1397 mm respectively) while the  $(Q_s/Q_t)$  ratio increased from 40.7 % to 45.2 %. Similarly, the mean annual rainfall amount in the 1990s (1522 mm) was great higher than the mean annual rainfall amount in the 2000s (1462 mm) while the  $(Q_s/Q_t)$  increased from 45.6 % to 46.2 %. In ~~contrary~~ contrast, climate indexes such as 99-percentile rainfall, SDII (ratio of total precipitation amount to R1mm), and R20mm ~~are increase~~ ing consistently from ~~the period~~ 1970 to the 2000s, as shown in Table 4. This indicates that the increasing of surface ~~run-off~~ runoff might be due to an increasing of number of extreme rainfall ~~extreme~~ events and rainfall intensity. In other words, this study revealed that ~~infiltration excess of overland flow dominates~~ the rainfall-runoff processes in the UBNRB, not ~~for~~ saturation excess of

5 overland flow. The contradiction from the previous studies might be ~~either~~ due either to the limitation of the SWAT- CN method when applied in monsoonal climates or ~~due to the~~ the overlooked of tillage activities, which ~~has~~ significantly impact ~~on~~ the soil infiltration rate ~~by the previous studies~~. ~~At the beginning of the rainy season,~~ e Extensive tillage activities are carried out across the basin at the beginning of the rainy season,; ~~As a result~~ soils get disturbed as a result, which can increase the infiltration rate ~~and~~ ultimate ~~finally~~ decrease the amount of rainfall converted to runoff.

10 Although, the CN method is easy to use and, provides acceptable results ~~in many cases~~ for discharge at the watershed outlet in many cases, researchers have concerns about ~~over~~ its use in watershed models (Steenhuis et al., 1995; White et al., 2011). The SWAT-CN model relies with a statistical relationship between soil moisture condition and CN value obtained from plot data in the United States with a temperate climate that was never tested in a monsoonal climate ~~where exhibiting~~ two extreme soil moisture conditions ~~exhibited~~. In monsoonal climates, long periods of rain can lead to prolonged soil saturation ~~whereas~~ he during the dry period, the soil dries out completely, which may not happen in temperate climates (Steenhuis *et al.*, 2009). Hence, further research ~~is necessary~~ that considers bio-physical activities such as tillage and seasonal effects ~~to on~~ soil moisture at representative watersheds of the basin is necessary ~~tfor~~ properly assessing the ~~the~~ rainfall-runoff processes properly.

## 6. Conclusions

20 ~~The objectives of~~ this study's objectives were to understand the long-term variations of rainfall and streamflow in ~~of~~ the UBNRB using statistical techniques (MK and Pettitt tests), ~~and~~ to assess the combined and isolated ~~single~~ effects of climate and LULC change using a semi-distributed hydrological model (SWAT). Although, the results of the MK test for ~~the~~ annual and long-~~rainy-~~ season rainfall and streamflow show an increasing trend in the UBNRB for the last 40 years ~~in the UBNRB~~, the magnitude of Sen's slope for streamflow is much larger than the Sen's slope of areal rainfall. Moreover, for the short-~~rainy-~~ season streamflow shows a statistically significant positive increase ing while the rainfall shows no change. The mismatch of trend magnitude between rainfall and streamflow could be attributed to the combined effect of LULC and climate change, associated with decreasing actual evapotranspiration (Ea) and increasing rainfall intensity and extreme events.

30 ~~The~~ LULC change detection was assessed by comparing the classified images. T ~~and~~ the result showed that the dominant process is largely the expansion of cultivated land and decrease in forest coverage. The rate of deforestation is high during the ~~period~~ 1973 ~~—~~ 1995 period,; T this is probably due to the severe drought that occurred in the mid-1980s and ~~due to~~ a large population increase ~~as a~~ resulting from the expansion of agricultural land. On the other hand, forest coverage increased by 3.4 % during the period 1995 to 2010. This indicates that the environment was recovering from the devastating drought ~~of~~

in the 1980s, ~~and~~ regenerating of forests as the result of afforestation programme initiated by the Ethiopian government, and due to soil and water conservation activities ~~accomplished~~ done by the communities.

The SWAT model was used to ~~analyse~~ analyze the combined and ~~isolated~~ single effects of LULC and climate changes on the monthly streamflow at the basin outlet (El Diem station, located on the Ethiopia-Sudan border). The result showed that the combined effects of the LULC and climate changes increased the mean annual streamflow by 16.9 % from the 1970s to the 2000s. The increased mean annual streamflow could be ascribed to the combined effects of LULC and climate change. The LULC change alters the catchment responses. ~~A~~ as a result, SWAT model parameter values could be changed. For instance, the expansion of cultivation land and the shrinkage of forest coverage from 1973 to 1995 ~~has~~ changed the CN2 parameter's values from 0.89 in 1973 to 0.91 and 0.92 in ~~the~~ 1985 and 1995 respectively. ~~The~~ increasing of CN2 value might increase surface ~~run-off~~ runoff and decrease base flow. Similarly, the increase in rainfall intensity and extreme precipitation events led to a substantial increase in  $Q_s/Q_t$ , ~~and~~ a substantial decrease in  $Q_b/Q_t$ , and ultimately ~~to~~ increases in the streamflow during the 1971–2010 simulation period.

The "fixing-changing" approach result using ~~the~~ SWAT model revealed that the ~~single~~ isolated effect of LULC change could potentially altered the streamflow generation processes. Expansion of cultivated land might reduce evapotranspiration because ~~transpiration for~~ seasonal crops ~~transpire~~ is less than ~~the transpiration of~~ perennial trees ~~do~~ (Yan et al., 2013) ~~as a~~ resulting in increased surface ~~run-off~~ runoff ~~increased~~. Alternatively, reduction of forest coverage may ~~reduce~~ cause a ~~reduction in~~ canopy interception of the rainfall, decrease the soil infiltration by increasing raindrop impacts, and reduce plant transpiration, which can significantly increase surface ~~run-off~~ runoff and ~~reducing~~ base-flow (Huang et al., 2013). In general, ~~a~~ 5.1 % reduction in forest coverage and ~~a~~ 4.6 % increase in cultivated land led to ~~a~~ 9.9 % increase ~~in~~ mean annual streamflow from 1973 to 1995. This study provides a better understanding and substantial information ~~about~~ how climate and LULC change affects streamflow and water balance components separately and jointly, which is useful for basin-wide water resources management. The SWAT simulation indicated that the impacts of climate change ~~are~~ is more substantial ~~as~~ ~~than~~ compared to the impacts of LULC change, ~~as~~ it is shown in Figure 7. Surface water is no ~~longer~~ any more used for agriculture and plant consumption in areas ~~such as the UBNRB~~, where ~~there is limited~~ water-storage facilities ~~are scarce~~, ~~like UBNRB where~~ ~~as~~ On the other hand, base flow ~~provides~~ is the ~~most~~ reliable sources for ~~the~~ irrigation ~~needed~~ to increase agricultural production. Hence, ~~the~~ the increasing amount of surface water and ~~diminished~~ reduction of base flow caused by both LULC and climate changes negatively affects ~~the~~ socio-economic developments ~~in~~ of the basin.

~~P~~Therefore, ~~protecting~~ and conserving the natural forests and expanding soil ~~and~~ water conservation activities ~~is~~ ~~therefore~~ are highly recommended, not only ~~t~~for increasing the base flow available for irrigation but also ~~to~~ ~~reducing~~ soil erosion. ~~By~~ doing so, ~~the~~ might increase productivity, ~~might be increased~~, and livelihoods ~~and~~ ~~as well as~~ regional ~~water~~ resource ~~use~~ cooperation might ~~be~~ improved. However, ~~this study might have limitations due to~~ the uncertainties of Landsat

image classification and the ~~SWAT-model~~ simulation ~~might limit this study-of-SWAT-model~~. ~~In order~~ to improve the accuracy of LULC classification from Landsat images, further efforts such as ~~the-integrating-on-of~~ other images ~~together~~ with Landsat images through image-~~fusion~~ techniques (Ghassemian, 2016) ~~are~~ required. The SWAT model does not adjust CN2 for slopes greater than 5% ~~;~~ ~~This~~~~which~~ could be significant in areas where the majority of the area has a slope greater than 5%, such as ~~in the~~ UBNRB. ~~W~~~~Therefore, we~~ ~~therefore~~ suggest adjusting ~~the~~ CN2 values for slope >5 % outside of the SWAT model might improve the results. Moreover, further research ~~that~~ ~~involving~~es rainfall intensity, infiltration rate, and event-based analysis of hydrographs and critical evaluation of rainfall-runoff processes in the study area might ~~overcome~~~~improve~~ this study's ~~limitations-of-this-study~~. Finally, the authors would like to point out that the impacts of current and future water resource developments should be investigated ~~in order~~ to establish comprehensive, ~~and~~ holistic water resource management in the Nile basin.

Acknowledgements. The authors would like to thank the Ethiopian Ministry of Water, Irrigation and Electricity and the Ethiopian National Meteorological Services Agency for providing the streamflow and meteorological data, respectively for free. The authors would also like to express their gratitude to the anonymous referees and the editor, Prof. Axel Bronstert, who gave constructive remarks and comments for enhancing the quality of the manuscript.

Table 1: ~~The UBNRB's Areal-areal~~ long term (1971–2010) mean annual and seasonal rainfall and streamflow ~~of UBNRB~~

Station	Amount				Contribution (%)			Mean	Area (km <sup>2</sup> )
	Kiremit	Belg	Bega	Total	Kiremit	Belg	Bega		
Flow (m <sup>3</sup> s <sup>-1</sup> )	3506.3	300.4	1018.4	4825.1	72.7	6.2	21.1	1608	172,254
Flow (BCM)	36.4	3.1	10.6	50.7					
Rainfall (mm)	1070.1	140.8	238.9	1449.8	73.8	9.7	16.5		

Kiremit: long rainy season, Belg: ~~Short-short~~ rainy season, Bega: ~~Dry-dry~~ season

Table 2: Data sets ~~offer~~ the baseline and altered periods for the SWAT simulation used to analyze ~~se~~ the combined and ~~isolatedsingle~~ effect of LULC and climate changes on streamflow and water balance components

Model run No.	Combined effect		Isolated LULC change effect		Isolated climate change effect		Remark
	Climate data set	LULC map	Climate data set	LULC map	Climate data set	LULC map	
1	1970s	1973	1970s	1973	1970s	1973	Base period altered
2	1980s	1985	1970s	1985	1980s	1973	<del>P</del> period1 altered
3	1990s	1995	1970s	1995	1990s	1973	<del>P</del> period2 altered
4	2000s	2010	1970s	2010	2000s	1973	<del>P</del> period3

Table 3: MK and Pettitt tests for the [UBNRB's](#) rainfall and streamflow ~~of UBNRB~~ after TFPW at different time scales

Time scale	Stream flow					Rainfall				
	p-value		Sen's slope:	Change point	Pettit test	p-value		Sen's slope	Change point	Pettit test
	After*	Before*				After*	Before*			
Daily	< 0.0001	< 0.0001	0.013	1987	Increasing	0.387	0.953	0.000	1988	Increasing
Monthly	< 0.0001	0.031	0.378		No change	0.010	0.640	0.009		No change
annually	< 0.0001	0.009	9.619	1995	Increasing	0.006	0.260	1.886		No change
Kiremit	< 0.0001	0.014	20.30		No change	0.010	0.348	1.364		No change
Belg	< 0.0001	0.004	3.593	1985	Increasing	0.822	0.935	0.068		No change
Bega	0.000	0.214	4.832		No change	0.527	0.755	0.169		No change

\* ~~B~~before and after TFPW; p: probability at 5% significance level

Table 4: Summary of [the UBNRB's](#) precipitation indices ~~of the UBNRB~~ at decadal time series

Indices	1970s	1980s	1990s	2000s
Mean (mm)	4.17	4.05	4.42	4.16
95 percentile (mm)	12.57	12.52	13.66	13.31
99 percentile (mm)	17.34	17.77	19.44	19.65
1-day max (mm)	27.15	25.67	32.24	32.38
R20mm (days)	16	15	30	35
SDII (mm/day)	7.22	7.38	7.66	7.77

5 | SDII is the ratio of total precipitation (mm) to R1mm (days).

Table 5: Confusion (error) matrix for the 2010 land use/cover classification map

LULC class	Water	Forest	Cultivated	Bushes and shrubs	Row total	Producers' accuracy
Water	44	0	0	0	44	100
Forest	1	46	6	8	61	75.4
Cultivated land	2	3	77	15	97	79.4
Bushes and shrubs	1	3	9	73	86	84.9
Column total	48	52	92	86	288	
User's accuracy (%)	91.7	88.5	83.7	84.9		
Over all accuracy(%)	<del>0.880</del>					
Kappa	0.77					

Table 6: ~~The SWAT model's~~ Statistical performance measure values ~~of the SWAT model~~

Period		R <sup>2</sup>	NSE	RVE (%)
1970s	Calibration (1973-1977)	0.79	0.74	-3.41
	Validation (1978-1980)	0.84	0.83	7.18
1980s	Calibration (1983-1987)	0.80	0.74	-0.72
	Validation (1988-1990)	0.86	0.82	0.73
1990s	Calibration (1993-1997)	0.91	0.91	1.79
	Validation (1998-2000)	0.87	0.84	-3.56
2000s	Calibration (2003-2007)	0.86	0.86	3.99
	Validation (2008-2010)	0.94	0.92	-7.51

Table 7: SWAT sensitive model parameters and their (final) calibrated values for the four model runs.

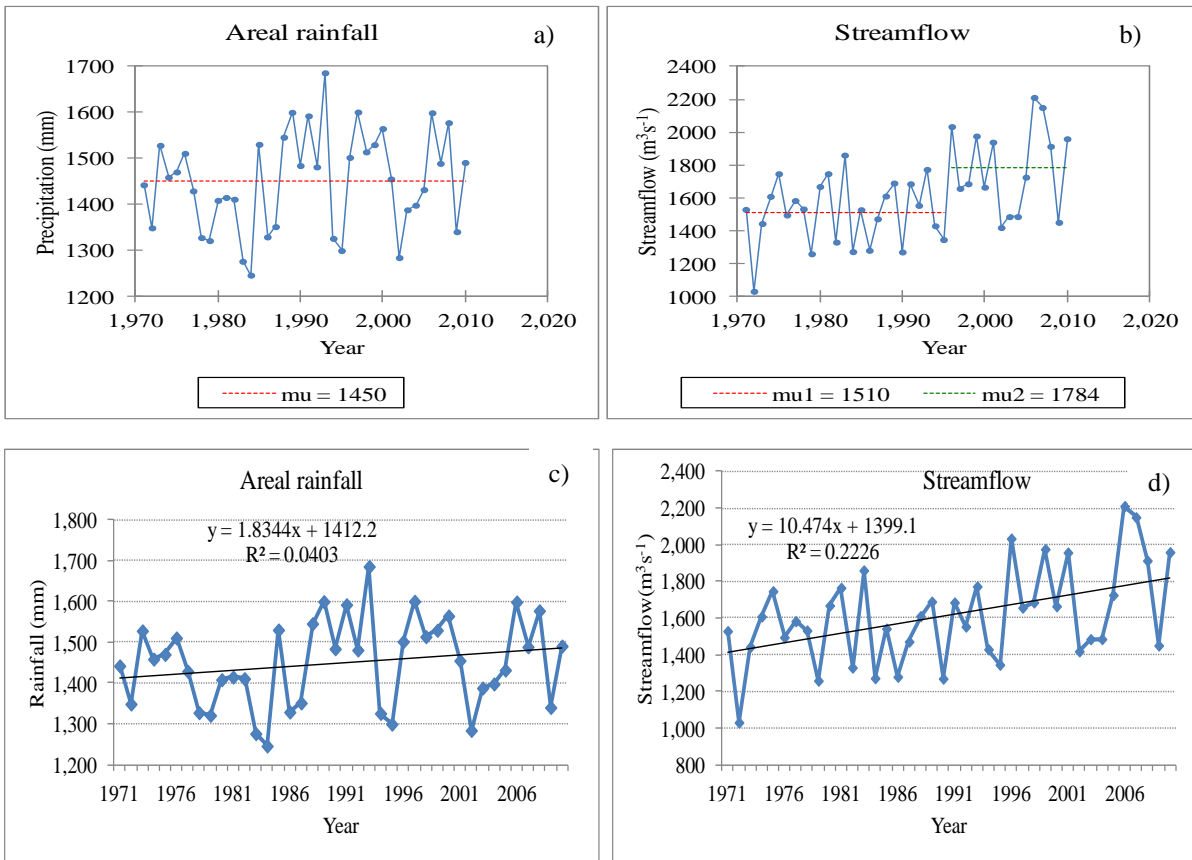

Parameter	Optimum value			
	1970s	1980s	1990s	2000s
R-CN2	0.88	0.91	0.92	0.9
a-Alpha-BF	0.028	0.028	0.028	0.028
V-GW_REVAPMN	0.7	0.45	0.7	0.34
V-GWQMN	750	750	750	750
V-REVAPMN	550	450	425	550
a-ESCO	-0.85	-0.85	-0.85	-0.85
R-SOL_AWC	6.5	6.5	6.5	6.5

R: value from the SWAT database is multiplied by a given value; V: Replace the initial parameter by the given value; a: Adding the given value to initial parameter value.

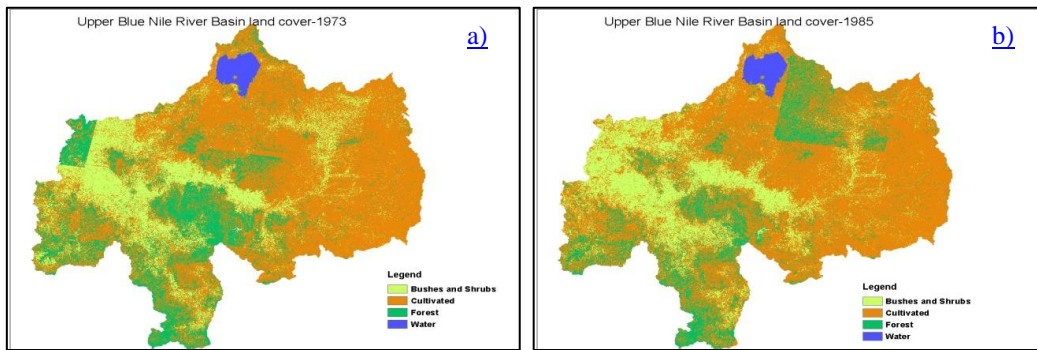

Table 8: Water balance components analysis in the Upper Blue Nile River Basin (mm/year) by considering LULC and climate change over respective periods. All streamflow estimates are for El Diem station.

Water balance components	1970s	1980s	1990s	2000s
Surface flow (Qs)	112.8	143.4	168.6	141.4
Lateral flow (Ql)	116.8	113.35	125.9	117.6
Base flow (Qb)	47.3	29.6	9.8	64.7
PET (mm)	1615.1	1627.3	1614.7	1732.9
Ea (mm)	871.6	852.6	904.3	885
Precipitation (P)	1428.1	1397.1	1522.2	1462.5
Total yield ( Qt)	276.9	286.3	304.3	323.7
Qs/Qt (%)	40.7	50.1	55.4	43.7
Qb/Qt (%)	17.1	10.3	3.2	20.0
Ea/P (%)	61.0	61.0	59.4	60.5
