The manuscript "Saturated Hydraulic Conductivity and Textural Heterogeneity of Soils" brings an interesting approach in predicting Ksat values based on IE and textural hetereogenity behaviour. A grand USDA data set was used to test this approach. However, I think that a comparison of the obtained Ksat results against other results published on literature (which have used other methods) would be very nice. It could be a simple table showing Rˆ2 and RMSE results with a text discussion for Ksat under the same textural classes ranging different methods and authors or other idea of authors. Thus, readers could have an idea of how is the performance of this method in front of other known methods. Title of this manuscript could be more specific about used method. I would write someting like: "Prediction of Saturated Hydraulic

Conductivity based on Textural Heterogeneity and Information Entropy of Soils". Some comments and details are presented in attached in other to help authors.
