7 **Abstract**

8 Wavelet coherence is a commonly used method in hydrology to extract scale-dependent, non-stationary relationships
9 between time series. However, we show that the method cannot always determine why the time-domain correlation
10 between two time series temporally changes. We show that even for stationary coherence, the time-domain correlation
11 between two time series weakens if at least one of the time series has changing nonlinear characteristics. To overcome
12 this drawback, a nonlinear coherence method is proposed for quantifying the cross-correlation between nonlinear
13 modes embedded in time series. It is shown that using nonlinear coherence spectra together with auto-bicoherence
14 spectra can provide additional insight into changing time-domain correlations. The new method is applied to the El
15 Niño /Southern Oscillation (ENSO) and All-India rainfall, which is closely linked to hydrological processes across
16 the India sub-continent. The nonlinear coherence analysis showed that the skewness of All-India rainfall is weakly
17 correlated with that of 4 ENSO time series after the 1970s, indicating that increases in ENSO skewness after the 1970s
18 at least partially contributed to the weakening All-India rainfall-ENSO relationship in recent decades. The implication
19 of this result is that the intensity of skewed El Niño events is likely to overestimate India drought severity, which was
20 the case in the 1997 monsoon season, a time point when the nonlinear wavelet coherence between All-India rainfall
21 and ENSO reached its lowest value in the 1871-2016 period. We determined that the association between the
22 weakening ENSO-All India rainfall relationship and ENSO nonlinearity could reflect the contribution of different
23 nonlinear ENSO modes to ENSO diversity.

24 **1. Introduction**

25 South Asian Monsoon, the dominant source of precipitation for the Indian subcontinent, has been a target for
26 seasonal prediction for well over a century (Blanford, 1884). Despite this long heritage of research, skillful prediction
27 remains a challenge, driving extensive and ongoing research on statistically and dynamically based prediction methods
28 (e.g., REFS). It is difficult to overstate the importance of the South Asian Monsoon to the well-being in India. Strong
29 monsoon years are associated with catastrophic flooding (Kale, 2012; Sanyal and Lu, 2005) and large landslides
30 (Dortch et al., 2009), while weak monsoons have led to water shortages (Mishra et al., 2016) and crop losses (Prasanna,
31 2014; Parthasarathy et al., 1988) that, in historical times, were known to result in significant food shortages (Fagan,
32 2009). Thus, while the majority of monsoon forecast studies target prediction of rainfall totals, the hydrological and
33 agricultural impacts of monsoon variability provide the most pressing motivation for the work.

34 Much of the research on South Asian Monsoon prediction has focused on the relationship between the El
35 Niño/Southern Oscillation (ENSO; Walker and Bliss, 1932) and monsoon strength. During El Niño years, droughts
36 are favored, while rainfall surpluses are favored during La Niña years (Shukla and Paolino, 1983; Kripalani and
37 Kulkarni, 1997). However, there is no one-to-one relationship between ENSO and Indian rainfall. As a result, summer
38 rainfall predictions based on ENSO have proven challenging. For example, the 1997/1998 El Niño event was
39 extremely strong yet climatological Indian monsoon conditions were observed (Shen and Kimoto, 1999; Slingo and
40 Annamalai, 2000). It is therefore important to understand why certain El Niño events are not accompanied by monsoon
41 failures.

42 There are a few reasons for the challenges faced when predicting Indian rainfall using ENSO. The first reason
43 is that the relationship between ENSO and India rainfall is non-stationary. As shown by Torrence and Webster (1999),
44 the relationship between ENSO and India rainfall cycles between periods of high and low coherence. Kumar et al.
45 (1999) found that the relationship between India rainfall and ENSO weakened in the 1970s and hypothesized that a

46 southward shift in Walker circulation anomalies associated with ENSO events and increased Eurasian spring and
47 winter surface temperatures was responsible for the weakening relationship. Other work suggests that the changing
48 ENSO-India rainfall relationship was the result of tropical Atlantic sea surface temperatures (SSTs) and the Atlantic
49 Multi-decadal Oscillation modulating the relationship (Lu et al., 2006; Kucharski et al. 2007; Kucharski et al., 2009;
50 Chen et al., 2010). In contrast, Kumar et al (2006) and Fan et al. (2017) argued that the occurrence of different ENSO
51 flavors (Johnson, 2013) such as the Eastern Pacific and Central Pacific types could explain the changes in the ENSO-
52 India rainfall relationship. Other investigators adopted another perspective to explain changes in the ENSO-India
53 rainfall relationship and concluded that temporal undulations in the ENSO-India rainfall relationship are related to
54 statistical under-sampling and stochastic fluctuations (Gershunov et al. 2001; van Oldenborgh and Burgers, 2005;
55 Delsole and Shukla, 2006; Cash et al., 2017). In a recent analysis, Yun and Timmermann (2018) showed that changes
56 in the ENSO-Indian rainfall relationship are consistent with a stochastically perturbed ENSO signal and argued that
57 changes in the ENSO-India monsoon relationship may not be related to external climate forcing mechanisms.

58 The second reason for the ENSO-related prediction challenges is that ENSO itself is a non-stationary
59 phenomenon. Using wavelet analysis, Kestin et al. (1998) found that the interannual variability of ENSO from 1930
60 to 1960 was dominated by a 4- to 7- year periodicity, whereas for the time period from 1960 to 1990, the interannual
61 variability was also dominated by a 2- to 5- year periodicity. A wavelet power spectral analysis conducted by Torrence
62 and Webster (1999) and Schulte (2016a) showed that ENSO signal energy in the 2- to 7-year period band undulates,
63 with the signal energy of the Niño 3.4 time series particularly pronounced after the 1960s (Schulte 2016a).

64 The nonlinear characteristics (e.g. skewness) of ENSO are also non-stationary and undergo interdecadal
65 changes (Wu and Hsieh, 2003). Numerous studies have reported an ENSO regime shift in the 1970s in which ENSO
66 began to evolve more nonlinearly than in previous decades (An, 2004; An and Jin 2004; An, 2009). It is a curious fact
67 that the ENSO regime shift of the 1970s coincided with the weakening ENSO-India rainfall relationship as
68 documented by Kumar et al. (1999). This observation begs the question as to whether nonlinear ENSO regime changes
69 are related to changes in the ENSO-India rainfall relationship.

70 Various mechanisms have been proposed for explaining ENSO skewness. Kang and Kug (2002) suggested
71 that the asymmetry between the magnitude of El Niño and La Niña events is related to the relative westward
72 displacement of zonal wind stress anomalies during La Niña events compared to El Niño events. Jin et al., (2003) and
73 An and Jin (2004) found that ENSO asymmetry is related to nonlinear dynamical heating (NDH), where the magnitude
74 of NDH is related to the propagation characteristics of ENSO. During strong El Niño events like the 1982/1982 and
75 1997/1998 events, SST anomalies were found to propagate eastward, with the eastward propagation tending to produce
76 more NDH compared to weak El Niño events when NDH is minimal (An and Jin, 2004). Since the late 1970s there
77 has been a propensity for eastward propagation characteristics of ENSO (Santoso et al., 2013), contrasting with the
78 time period before the 1970s that consisted of the relatively weak El Niño events of 1957/1958 and 1972/1973 (An
79 and Jin, 2004; An, 2009). More recently, Su et al. (2010) showed that vertical temperature advection may have an
80 opposing effect on ENSO asymmetry and that the asymmetry in the extreme eastern equatorial Pacific is related to
81 meridional ocean temperature advection.

82 Previous investigators have used different metrics to quantify ENSO asymmetry. To measure the nonlinear
83 character of ENSO, An and Jin (2004) used time-domain metrics such as skewness and maximum potential intensity
84 (MPI) to quantify the skewness of SST anomalies and the skewness of individual ENSO events, respectively. An
85 (2004) applied a principal component analysis (PCA) to a 21- year moving window of tropical Pacific SST skewness
86 and found that the first PCA mode is characterized by positive skewness across the eastern equatorial Pacific and
87 negative skewness across the central equatorial Pacific. This pattern means that interdecadal changes in the
88 nonlinearity of ENSO is associated with positively skewed SST anomalies across the eastern equatorial Pacific,
89 implying that El Niño events are stronger than La Niña events. While the methods implemented in the aforementioned
90 studies provided important insights, they cannot reveal the frequency modes of ENSO that are contributing to the
91 skewness.

92 Recognizing the limitations of time-domain approaches, Timmermann (2003) conducted a bi-spectral
93 analysis of the Niño 3 anomaly time series, where a peak (f_1, f_2) in the bi-spectrum means there is statistical phase
94 dependence among oscillators with frequencies f_1 , f_2 , and $f_1 + f_2$. That bi-spectral analysis revealed statistically

95 significant bi-spectral power at several frequency pairs, including (0.038, 0.038), (0.028, 0.028), (0.0225, 0.0225),
 96 (0.0045, 0.032), and (0.0045, 0.045) [month⁻¹]. The peaks (0.0045, 0.032), and (0.0045, 0.045) [months⁻¹] were
 97 identified with the nonlinear interactions among 18-year and 2-year variability. Although the analysis provided new
 98 insights, the Fourier-based analysis could not reveal how the nonlinear nature of ENSO changed with time, an
 99 important property to capture given how the nonlinear characteristics of ENSO are non-stationary (Santoso et al.,
 100 2013). Much like the cross-wavelet power (Maraun and Kurths, 2004) and time-domain covariance, bi-spectral power
 101 is not a bounded quantity and so high bi-spectral power does not always mean strong phase dependence.

102 In this study, the deficiencies associated with the above-mentioned techniques are addressed using higher-
 103 order wavelet analysis, which allows for the quantification of frequency-dependent and non-stationary nonlinearities
 104 in time series (Van Millagan, 2004, Elsayad, 2006; Schulte, 2016b). More specifically, the objectives of the paper are
 105 the following: 1) quantify the nonlinearity of ENSO using higher-order wavelet analysis together with recently
 106 developed statistical tests; (2) Determine if different nonlinear modes of ENSO are associated with distinct SST
 107 patterns; and (3) develop nonlinear wavelet coherence methods to test the hypothesis that the breakdown of the ENSO-
 108 India rainfall relationship in recent decades is related to the shift of ENSO from a linear regime to a nonlinear one.
 109 The paper is organized as follows: In Section 2, data used are described. Section 3 includes the description of the
 110 implemented methodologies. Results are presented in Section 4 and concluding remarks are provided in Section 5.

111 2. Data

112 The variability of India rainfall from 1871-2016 was analyzed using the All-India rainfall (AIR; Parthasarathy
 113 et al. 1994) time series, which was created by averaging representative rain gauges at various locations across India.
 114 The full monsoon season (June-September) and the late monsoon (August-September) season were used to identify
 115 possible within-season variations in the ENSO-All-India relationships. To remove the influence of the annual cycle,
 116 AIR time series was converted into anomaly time series by subtracting the 1871-2016 long-term mean for each month
 117 from the individual monthly values. The AIR anomaly (AIR, hereafter) time series were subsequently standardized
 118 by dividing it by its 1871-2016 standard deviations. Because wavelet analysis focuses on specific frequency
 119 components that are not impacted by long-term time-domain trends, no detrending of the data was performed.

120 The monthly data for the Niño 1+2, Niño 3, Niño 3.4, and Niño 4 indices (available at:
 121 https://www.esrl.noaa.gov/psd/gcos_wgsp/Timeseries/Data/nino34.long.data) from 1871 to 2016 were used to
 122 understand how the nonlinear characteristics of SSTs varied from one ENSO region to another. The Niño 1+2 index
 123 is the average SST in the region with latitudinal boundaries 0° and 10°S and longitudinal boundaries 90°W and 80°W
 124 and the Niño 3 index is the average SST in the region with latitudinal boundaries 5°N and 5°S and longitudinal
 125 boundaries 150°W and 90°W. Variations in SSTs further west were described using the Niño 3.4 and Niño 4 indices,
 126 where the Niño 3.4 index is defined as the average SST in the region bounded by 5°N and 5°S and 170°W and 120°W
 127 and the Niño 4 index is defined as average SSTs in the region bounded by 5°N and 5°S and 160°E and 150°W. The
 128 seasonal cycle was removed from these time series in the same way as it was removed from the All-India rainfall time
 129 series.

130 The monthly SST data from 1871-2016 were based on the Hadley Centre Global Sea Ice and Sea Surface
 131 Temperature (HadISST1; Rayner et al., 2003) The data at each grid point were converted to monthly anomalies in the
 132 same way as they were computed for the ENSO and All-India time series.

133 3. Methods

134 3.1 Wavelet Analysis

135 To better diagnose changes in time series statistics associated with AIR and ENSO, we adopted a wavelet
 136 analysis. For a time series, X , comprising data points x_1, x_2, \dots, x_N , the continuous wavelet transform is given by

$$137 \quad W_n(s) = \sqrt{\frac{\delta t}{s}} \sum_{n'=1}^N x_{n'} \psi_0 \left[(n' - n) \frac{\delta t}{s} \right] \quad (1)$$

138 where s is wavelet scale, ψ_0 is an analyzing wavelet, δt is a time step (1 month in this study), and n is time. The
 139 sample wavelet power spectrum $|W_n(s)|^2$ measured the energy content of a signal at time n and scale s . The commonly
 140 used Morlet wavelet with angular frequency $\omega = 6$ was used throughout this paper because it balances time and
 141 frequency localization and because it is commonly used in hydrological and climate studies (Schaeffli et al., 2007;
 142 Zhang et al., 2007; Holman et al., 2001; Carey et al., 2013). The reader is referred to Torrence and Compo (1998) and
 143 Grinsted et al. (2004) for more details about wavelet analysis.

144 Linear wavelet coherence (Table 1) was used to quantify the linear relationship between two time series as a
 145 function of frequency and time. Linear wavelet coherence between two time series X and Y is given by

$$146 \quad R_n^2(s) = \frac{|Ss^{-1}W_n^{XY}(s)|^2}{s(s^{-1}|W_n^X(s)|^2)s(s^{-1}|W_n^Y(s)|^2)}, \quad (2)$$

147 where S is a smoothing operator (Grinsted et al., 2004) and $W_n^{XY}(s)$ is the cross-wavelet power spectrum. Two time
 148 series are perfectly coherent ($R_n^2(s) = 1$) at s if $\phi_n^X(s) - \phi_n^Y(s) = c$ over a sufficiently long time interval, where c is
 149 a constant, $\phi_n^X(s)$ is the phase associated with X , and $\phi_n^Y(s)$ is the phase associated with Y .

150 In the context of the Indian monsoon, strong coherence between rainfall and a climate pattern (e.g. ENSO)
 151 at a scale s indicates shared temporal characteristics between a climate pattern and rainfall. Because theory supports a
 152 causal link between ENSO and monsoon variability through changes in the Walker Circulation (Ropelewski and
 153 Halpert, 1987), strong coherence means that when ENSO is in a warm (cool) phase at the scale s , negative (positive)
 154 rainfall anomalies are preferred. Thus, a periodic climate forcing could create periodicities in an otherwise noisy
 155 rainfall time series.

156 3.2 Higher-order Wavelet Analysis

157 Although the wavelet power spectrum is useful for quantifying the signal energy at a scale s and time n , it
 158 cannot determine if there is a nonlinear relationship among different frequency components. In fact, the power
 159 spectrum can only fully describe time series in frequency space in the case of linear systems in which the output is
 160 proportional to the input (King, 1998). As ENSO is nonlinear, we adopted higher-order wavelet methods to address
 161 the deficiencies of traditional wavelet methods.

162 The type of nonlinearities considered in this study were quadratic nonlinearities in which the scales s_1 , s_2 ,
 163 and s_3 satisfied the sum rule

$$164 \quad \frac{1}{s_3} = \frac{1}{s_1} + \frac{1}{s_2} \quad (3)$$

165 and the wavelet phases satisfied

$$166 \quad \phi_n(s_3) = \phi_n(s_1) + \phi_n(s_2). \quad (4)$$

167 These types of nonlinearities arise, for example, when a sinusoid is squared, in which case a harmonic is produced.

168 In this paper, quadratic nonlinearities giving rise to time series skewness were quantified using local and
 169 global wavelet-based auto-bicoherence methods (Schulte, 2016b). Global auto-bicoherence (Table 1) was computed
 170 using the equation

$$171 \quad bi_{global}^X(s_1, s_2) = \frac{|B_{global}^X(s_1, s_2)|^2}{(\sum_{n=1}^N |W_n^X(s_1)W_n^X(s_2)|^2)(\sum_{n=1}^N |W_n^X(s_3)|^2)}, \quad (5)$$

172 where

$$173 \quad B_{global}^X(s_1, s_2) = \sum_{n=1}^N \widehat{W}_n^X(s_3)W_n^X(s_1)W_n^X(s_2) \quad (6)$$

174 is the global bi-spectrum and the hat denotes the complex conjugate. Identical to wavelet coherence, auto-bicoherence
 175 is bounded by 0 and 1, a value of 1 indicating the strongest possible phase coupling among the phases $\phi_n(s_3)$, $\phi_n(s_2)$,

176 and $\phi_n(s_1)$ such that sum rule Eq. (4) is satisfied. A peak in the auto-coherence spectrum at (s_1, s_2) means there is
 177 quadratic phase coupling between oscillatory modes with scales s_1 , s_2 , and s_3 so that the oscillatory modes are
 178 contributing to the skewness of the time series. It is important to note that the auto-bicoherence cannot detect other
 179 types of nonlinearities such as cubic nonlinearities whose detection would require trispectra (Collis et al., 1998).

180 To determine if the strength of the quadratic phase coupling changed temporally, the local auto-bicoherence
 181 spectrum (Schulte, 2016b) given by

$$182 \quad bi_n^X(s_1, s_1) = \frac{|s_{s_1}^{-1} B_{local}(s_1, s_1)|^2}{s(s_{s_1}^{-1} |W_n^X(s_1) W_n^X(s_1)|^2) s(s_{s_1}^{-1} |W_n^X(\frac{s_1}{2})|^2)} \quad (7)$$

183 was computed, where $B_n^X(s_1, s_2)$ is the local bi-spectrum given as

$$184 \quad B_n^X(s_1, s_1) = \widehat{W}_n^X(s_3) W_n^X(s_1) W_n^X(s_1). \quad (8)$$

185 and $s_3 = s_1/2$. In this special case, the local auto-bicoherence spectrum revealed the time-evolution of auto-
 186 bicoherence estimates located along the diagonal slices of the global auto-bicoherence spectra. Local bi-phase

$$187 \quad \psi_n(s_1, s_2) = \phi_n(s_1) + \phi_n(s_2) - \phi_n(s_3) \quad (9)$$

188 was used to measure the skewness and asymmetries of waveforms. A bi-phase of 0° meant that the relationship among
 189 the scale components produced positive skewness with respect to a horizontal axis so that positive deviations from the
 190 mean are larger than negative deviations from the mean. On the other hand, a bi-phase of 180° indicated negative
 191 skewness with respect to the mean. Bi-phases near -90° or 90° indicated the presence of asymmetric cycle geometry
 192 (King, 1998; Maccarone, 2014; Schulte, 2016b) such that a time series rose (fell) more quickly than it fell (rose).

193 To be consistent with the wavelet power and coherence analyses, results for the higher-order wavelet analysis
 194 were casted in terms of Fourier period rather than wavelet scale. The Fourier period corresponding to s_i was denoted
 195 by p_i , where the Fourier period is obtained by multiplying s_i by 1.03 for the Morlet wavelet (Torrence and Compo,
 196 1998). Thus, the local diagonal slice of the auto-bicoherence spectra were plotted using the Fourier period p_1
 197 corresponding to s_1 as the vertical axis and time as the horizontal axis.

198 3.3 Statistical Hypothesis Testing

199 The statistical significance of all wavelet spectra was evaluated using the cumulative area-wise test (Schulte,
 200 2016a; Schulte, 2019) to account for the simultaneous testing of multiple hypotheses (Maraun and Kurths, 2004;
 201 Maraun et al., 2014). This test evaluated the statistical significance of points in the wavelet domain based on the area
 202 of contiguous regions of point-wise significance (i.e. patches) to which they belong so that larger area implies greater
 203 statistical significance. Given that patch area can change as the point-wise significance changes, the cumulative area-
 204 wise test was used to evaluate significance based on the area of a patch averaged across a set of point-wise significance
 205 levels (Schulte, 2019). The test was applied at the 5% cumulative area-wise significance level using point-wise
 206 significance levels ranging from 0.02 to 0.18 because this choice of point-wise significance levels was shown to result
 207 in the cumulative area-wise test outperforming the point-wise test in terms of true positive detection for high signal-
 208 to-noise ratios even though the cumulative area-wise test is more stringent. The test was performed using the Advanced
 209 Biwavelet Wavelet R software Package (available at: <http://justinschulte.com/wavelets/advbiwavelet.html>). Technical
 210 details of the testing procedure can be found in Schulte (2019) and in Appendix A.

211 To assess the statistical significance of the global auto-bicoherence estimates, a modified version of the
 212 cumulative area-wise test was applied. In the modified version of the cumulative area-wise test, the normalized area
 213 of patches was computed by dividing patch area by the product $\widehat{s}_1 \widehat{s}_2$, where \widehat{s}_1 is the mean first-coordinate of the patch
 214 and \widehat{s}_2 is the mean second coordinate. The reason for this modified normalized area is that dividing area by say, \widehat{s}_1^2 ,
 215 retained the correlation between normalized area and s_2 . The test was applied using the same point-wise significance
 216 levels that were used to assess the statistical significance of wavelet power and coherence.

217 3.5 Higher-order Coherence

218 Although wavelet coherence spectra can provide information regarding how the relationship between two
 219 climate variables changes at a scale s , it cannot completely explain why the time-domain correlation between the
 220 climate variables temporally fluctuates. The reason is that linear wavelet coherence only examines how well the
 221 variance of one time series corresponds to the variance of another at a scale s (Table 1) because linear coherence is
 222 determined by the wavelet power spectra of the time series. However, for two time series to be perfectly correlated in
 223 the time domain, higher skewness of one climate variable must also correspond to higher skewness of the other climate
 224 variable.

225 Recognizing that skewness is important for better understanding time-domain correlation changes, the
 226 quantity

$$227 \quad Bi_n^2(s) = \frac{|s_{smooth}^{-1} B_n^{XY}(s_1, s_2)|^2}{s(s_{smooth}^{-1} |B_n^X(s_1, s_2)|^2) s(s_{smooth}^{-1} |B_n^Y(s_1, s_2)|^2)}, \quad (10)$$

228 called third-order coherence (nonlinear coherence, hereafter) was used to determine if changes in the skewness of X
 229 are associated with changes in the skewness of Y (see Appendix B for a more general definition). In Eq. (10), s_{smooth}
 230 is one of the three scales, and $B_n^{XY}(s_1, s_2)$ is the third-order cross-wavelet power spectrum, which is the product of the
 231 bi-spectrum of X and the conjugate of the bi-spectrum of Y , the higher-order analog of the cross-wavelet power
 232 spectrum. The word cross-bispectrum was not used to avoid confusion with cross-bicoherence analysis (Van
 233 Milligen, 1995). Like wavelet coherence, the nonlinear coherence is bounded by 0 and 1, a value of 1 indicating that
 234 the bi-spectra of X and Y at (s_1, s_2) are perfectly and linearly correlated. The statistical significance of nonlinear
 235 coherence was assessed using Monte Carlo methods and the cumulative area-wise test in the same way as it was used
 236 to assess the statistical significance of linear wavelet coherence.

237 Another way to interpret higher-order wavelet coherence is using linear and nonlinear modes. A linear mode
 238 $\gamma_{s_i}^X$ is the signal component of X at the scale s_i obtained by setting all wavelet coefficients to zero except those at s_i
 239 and taking the inverse wavelet transform of the result. Because linear modes are only composed of a single frequency
 240 component, the local cross-correlation (coherence) between $\gamma_{s_i}^X$ and $\gamma_{s_i}^Y$ is only impacted by the variances of X and Y
 241 at s_i . On the other hand, nonlinear coherence measures the local cross-correlation between the skewness of $\gamma_{s_1}^X + \gamma_{s_2}^X +$
 242 $\gamma_{s_3}^X$ and $\gamma_{s_1}^Y + \gamma_{s_2}^Y + \gamma_{s_3}^Y$ or between $\gamma_{s_1}^X + \gamma_{s_1/2}^X$ and $\gamma_{s_1}^Y + \gamma_{s_1/2}^Y$ in the case that $s_1 = s_2$.

243 To better understand nonlinear coherence, we supposed that

$$244 \quad \phi_n^X(s_1) - \phi_n^Y(s_1) = c_1 \quad (11)$$

$$245 \quad \phi_n^X(s_2) - \phi_n^Y(s_2) = c_2 \quad (12)$$

$$246 \quad \phi_n^X(s_3) - \phi_n^Y(s_3) = c_3 \quad (13)$$

247 for constants c_1 , c_2 , and c_3 . Adding Eqs. (11) and (12) and subtracting Eq. (13) from the result produced the equality

$$248 \quad \phi_n^X(s_1) + \phi_n^X(s_2) - \phi_n^X(s_3) - (\phi_n^Y(s_1) + \phi_n^Y(s_2) - \phi_n^Y(s_3)) =$$

$$249 \quad \psi_n^X(s_1, s_2) - \psi_n^Y(s_1, s_2) = \psi_n^{bi}(s_1, s_2) = K, \quad (14)$$

250 for some constant $K = c_1 + c_2 - c_3$. Thus, if X is perfectly nonlinear coherent with Y , then X and Y must be perfectly
 251 coherent at the three scales participating in the quadratic phase coupling. Even if the coherence is perfect at two scales,
 252 the relative bi-phase $\psi_n^{bi}(s_1, s_2)$ will fluctuate randomly if the relative phase difference at the remaining scale
 253 fluctuates randomly so that the nonlinear coherence will be low. Thus, if nonlinear coherence is high, then there must
 254 be some non-random relationship between X and Y at all three scales even if high linear coherence was not identified
 255 at one or more scales, indicating that nonlinear coherence can uncover relationships that linear coherence cannot (see
 256 Figure S1 in supplementary material).

257 The relative bi-phase difference $\psi_n^{bi}(s_1, s_2)$ is the higher-order analog of the relative phase difference
 258 between two time series. It measures how much the cycle geometry of one time series lags that of another. A lagged

259 bi-phase of 180° means that the skewness or asymmetry of the forcing time series is opposite to that of the response.
 260 For example, if the forcing has positive skewness, then the response will have negative skewness. If the relative bi-
 261 phase is 0° , then negative (positive) skewness of the forcing produces negative (positive) skewness of the response,
 262 contributing to the positive time-domain correlation between the time series. Scales and time points for which
 263 nonlinear coherence is high are where the relative bi-phase is stable.

264 Throughout this paper, we will focus on nonlinear coherence computed along the diagonal slices ($p_1 = p_2$)
 265 of the time series bi-spectra. The nonlinear coherence spectra are then plotted using p_1 as the vertical axis and time as
 266 the horizontal axis. High nonlinear coherence at p_1 and n means that the skewness or asymmetry between $\gamma_{p_1}^X + \gamma_{p_1/2}^X$
 267 and $\gamma_{p_1}^Y + \gamma_{p_1/2}^Y$ are locally cross-correlated.

268 To demonstrate the concept of nonlinear coherence, we considered a simple example in which the nonlinear
 269 climate forcing time series was given by

$$270 \quad F(t) = \cos\left(\frac{2\pi}{p_1} t + \phi\right) + \gamma(t) \cos\left(\frac{2\pi}{p_3} t + 2\phi\right) + W_F(t) \quad (15)$$

271 and the response to the forcing was given as

$$272 \quad R(t) = \cos\left(\frac{2\pi}{p_1} t + \phi\right) + w_R(t), \quad (16)$$

273 In Eq. (15), $\gamma(t)$ is a time-varying nonlinear coefficient, $w_F(t)$ is Gaussian white noise associated with the forcing,
 274 $w_R(t)$ is Gaussian white noise associated with the response, $\phi = 0$ is phase, and $p_1 = 2p_3 = 32$. The nonlinear
 275 coefficient was assumed to be a linear function of time, i.e.,

$$276 \quad \gamma(t) = t/500. \quad (17)$$

277 The effect of the coefficient is to linearly increase the variance of $F(t)$ at $p_3 = 16$ and increase the strength of the
 278 quadratic phase coupling between the modes with periods $p_3 = p_1/2 = 16$ and $p_1 = 32$.

279 As shown in Figure 1a, $F(t)$ (black curve) and $R(t)$ (thick green curve) evolve coherently from $t = 0$ to $t =$
 280 200. After $t = 200$, $F(t)$ begins to noticeably exceed $R(t)$ at certain time points (e.g. $t = 430$) while the relationship
 281 between them at other points is reversed (e.g. $t = 450$) in the sense that a positive forcing produces a negative response.
 282 As a result, the correlation between $F(t)$ and $R(t)$ weakens (Figure 1b). An inspection of the wavelet coherence
 283 spectrum (Figure 2a) reveals that the coherence at $p_1 = 32$ is strong and stable so that changes in the relationship
 284 strength at that time scale is not the cause of the weakening time-domain correlation. The coherence at all other periods
 285 is also stationary by construction so that it is not the changing relationship strength at any scale that is causing the
 286 time-domain correlation weakening. However, the variance of $F(t)$ at $p_3 = 16$ increases with time (not shown) and
 287 the coherence between $F(t)$ and $R(t)$ is also weak at that time scale, implying that larger fluctuations in $F(t)$ at $p_3 = 16$
 288 are not accompanied by larger fluctuations in $R(t)$. Thus, variance increase of $F(t)$ is one reason for the weakening
 289 time-domain correlation, though the linear coherence and wavelet power methods cannot explain why the skewness
 290 of $F(t)$ increases without a corresponding increase in the skewness of $R(t)$ (Figure 1c).

291 An inspection of the local auto-bicoherence spectrum of $F(t)$ (Figure 2b) reveals that the auto-bicoherence at
 292 $p_1 = 32$ is increasing with time, indicating that the phase coupling between modes with periods $p_3 = 16$ and $p_1 = 32$
 293 is strengthening with time. The bi-phase of 0° , as indicated by arrows pointing to the right, confirms that the quadratic
 294 phase coupling is contributing to the positive skewness seen in Figure 1a to an increasing degree. Furthermore, the
 295 nonlinear coherence between $R(t)$ and $F(t)$ is weak and mostly statistically insignificant at $p_3 = 32$ (Figure 2c),
 296 implying the skewness of $\gamma_{16}^F + \gamma_{32}^F$ is uncorrelated with the skewness of $\gamma_{16}^R + \gamma_{32}^R$, where $\gamma_{16}^F + \gamma_{32}^F$ is the sum of the
 297 cosines in Eq. (15) and the components of $W_F(t)$ at $p_3 = 16$ and $p_1 = 32$. The nonlinear mode $\gamma_{16}^R + \gamma_{32}^R$ is the sum of
 298 the cosine in Eq. (16) and the components of $w_R(t)$ at $p_3 = 16$ and $p_1 = 32$. Thus, the skewness of $R(t)$ in the time-
 299 domain is practically uncorrelated with the skewness of $F(t)$ because the skewness of $F(t)$ is solely related to the phase
 300 coupling between the modes with periods $p_3 = 16$ and $p_1 = 32$. Thus, the increase in skewness of $F(t)$ also contributes
 301 to the weakening time-domain correlation.

302 The lack of nonlinear coherence at time scales for which $F(t)$ is nonlinear has implications for empirical
303 prediction. At time points when $F(t)$ is positively skewed $R(t)$ is overestimated because $R(t)$ is not inheriting the
304 skewness of $F(t)$. That is, if one created a linear regression model based on the relationship between $F(t)$ and $R(t)$ from
305 $t = 0$ to $t = 200$ one would find that a forcing value of, say, 1 would produce a response close to 1. If the same model
306 was used to predict $R(t)$ at, say, $t = 430$ one would predict that the forcing with value around 2 should result in a
307 response near 2. However, because the relatively large value $F(430)$ results from skewness and $R(t)$ is uncorrelated
308 with its skewness, the response is only as strong as the part of $F(t)$ not resulting from the quadratic phase coupling.
309 The more nonlinear $F(t)$ becomes, the more $F(t)$ will overestimate $R(t)$ when $F(t)$ is positively skewed. Similarly, the
310 positive forcing produces a negative response at $t = 450$ because of skewness and not simply a change in variance.
311 Nonlinear coherence allows for the quantification and identification of these time-domain aberrations.

312 The weakening relationship shown in Figure 1b could lead a researcher studying a hydrological process to
313 believe that another direct forcing mechanism must be influencing the hydrological process. This belief could lead to
314 the applications of partial coherence (Ng, and Chan, 2012) and partial correlation analyses to identify another
315 influential forcing mechanism. However, in this case, there are no other direct forcing mechanisms; the weakening
316 time-domain relationship is solely related to how $F(t)$ transitioned from a linear regime to a nonlinear regime. This
317 theoretical result suggests that hydrological studies using wavelet coherence should also consider the nonlinearity of
318 the times series.

319 4. Results

320 4.1 ENSO and Indian Monsoon time series

321 The contrasting Niño 1+2 and Niño 4 indices are shown in Figures 3. For the Niño 1+2 time series (Figure
322 3a), a few recent notably intense warm events are located around 1982/1983, 1997/1998, and 2015/2016 coinciding
323 with the strongest El Niño events in recent decades (McPhaden, 1999, Hu and Fedorov, 2017; Santoso et al, 2017).
324 The 1982/1983 and 1997/1998 warm events are not as pronounced in the Niño 4 time series (Figure 3b). A few notably
325 intense Niño 1+2 events are also seen in the late 1800s, indicating that intense ENSO events are not unique to recent
326 decades. An inspection of Figure 3a also reveals that the recent intense warm Niño 1+2 events are also skewed in the
327 sense that they are stronger than the surrounding cool Niño 1+2 events. In contrast, there is tendency for cool Niño 4
328 events to be stronger than the warm events after the 1960s, suggesting that the negative skewness has intensified.

329 The 20-year sliding skewness time series of the Niño 1+2 index (Figure 4) reveals enhanced skewness during
330 the early 1880s, near zero skewness around the 1930's and early 1940's, and especially enhanced skewness after the
331 1970s associated with an upward trend in skewness beginning around the 1940s. In contrast to the Niño 1+2 index,
332 the skewness of the Niño 4 index becomes more negative after the 1960s, and the magnitude of the skewness is
333 generally smaller than that of the Niño 1+2 time series. This finding suggests that the transition of the Niño 1+2 time
334 series to a nonlinear regime was more pronounced than the transition associated with the Niño 4 time series.

335 Interestingly, a 20-year sliding skewness analysis of AIR (Figure 4) reveals that the skewness of June-
336 September AIR remains close to zero until the 1990s despite the upward trend in Niño 1+2 skewness beginning in the
337 1940s (Figure 4a). Similarly, the skewness of August-September AIR does not increase to the extent that Niño 1+2
338 skewness does (Figure 4b), though the skewness could be negatively correlated with the skewness of the Niño 4 index
339 after the 1960s, consistent with how August-September AIR and the Niño 4 index are negatively correlated. The
340 skewness of June-September AIR becomes more negative in the 1990s and 2000s, but it is unclear if that negative
341 skewness is related to ENSO, noise, or another climate pattern because the skewness of the Niño 1+2 and Niño 4
342 indices do not change as abruptly. Negative June-September AIR skewness is accompanied by enhanced positive
343 skewness of the Niño 1+2 indices prior to the 1940s, which is consistent with how June-September AIR is negatively
344 correlated with the Niño 1+2 index time series during that time period (Figures 5a).

345 4.2 The time-domain Indian Rainfall-ENSO Relationship.

346 The differences in skewness shown in Figure 4 suggests that the correlation between the ENSO time series
347 and AIR degrades after the 1970s, which is confirmed by the 20-year sliding correlation between June-September AIR
348 and ENSO indices (Figure 5a). The relationship with the Niño 1+2 generally weakens from the 1800's to the 2000s.

349 In contrast, the June-September AIR-Niño 4 index relationship appears to have no long-term trend, resulting in the
350 Niño 4 index becoming more strongly correlated with AIR than the Niño 1+2 index after the 1970's. The relationship
351 between AIR and time series for the Niño 3 and Niño 3.4 indices are also relatively weak after the 1970s (not shown).

352 The stronger AIR-Niño 4 index relationship compared to the AIR-Niño 1+2 index relationship after the
353 1970s is more evident in the August-September analysis (Figure 5b). An abrupt weakening of the August-September
354 AIR-Niño 1+2 index relationship occurs around the 1970's, with the relationship reversing around the 1990s. A
355 comparison of Figures 4b and Figures 5b reveals that the weakening and reversal of the relationship occurs during the
356 time period when the Niño 1+2 index is especially skewed. The greater magnitude of the Niño 1+2 skewness compared
357 to that of Niño 4 skewness after the 1970s could explain why the August-September AIR-Niño 1+2 index relationship
358 weakens more abruptly than the AIR-Niño 4 index relationship. Thus, a further investigation is needed to better
359 understand the temporal changes in ENSO statistics and their impact on the ENSO-AIR relationship.

360 **4.3. Wavelet Power Analysis and Coherence**

361 The wavelet power spectra associated with the ENSO time series (Figure 6) reveal enhanced variance in the
362 16- to 64-month band after 1965 for all the time series. For the Niño 3 and Niño 4 time series, there is also enhanced
363 variance in the 16- to 64-month period band from 1875 to 1895. The appearance of holes in contoured regions suggests
364 that there are oscillatory modes with nearby frequencies (Schulte, et al., 2015), though the wavelet power spectra
365 cannot determine if there is quadratic phase coupling between the oscillatory modes.

366 The linear wavelet coherence spectrum shown in Figure 7, indicates that the AIR relationship with the Niño
367 1+2 and Niño 4 indices in the 16- to 64-month period band breaks down after 1995, which is consistent with the
368 findings from the sliding correlation analysis shown in Figure 5. The relationship between AIR and these ENSO
369 indices also weakens around 1925, but this weakening does not appear in the sliding correlation analysis. Note that
370 the lack of linear coherence after 1995 coincides with the enhanced ENSO variance (Figure 6), implying that higher
371 ENSO variance need not be associated with higher AIR variance at those time scales so that changes in ENSO variance
372 could be contributing to the weakening ENSO-AIR time-domain correlation. However, ENSO skewness is also
373 enhanced during this time period (Figure 4) so that weakening relationships may not be simply related to ENSO
374 variance. Thus, a further analysis is needed to extract information unrevealed by the linear wavelet power and
375 coherence methods.

376 **4.3 Local auto-bicoherence of ENSO**

377 Figure 8 shows that the local auto-bicoherence spectra of all ENSO time series contain statistically significant
378 local auto-bicoherence, but the spectrum of the Niño 4 index is only associated with a few statistically significant
379 regions such as the one around 2015 at a period of 32 months. For the Niño 3 and Niño 3.4 time series, two features
380 of interest are seen in the time period extending from 1973 to 2016 in the 16- to 64-month period band. The first
381 feature is the time-elongated region of statistical significance extending from 1973 to 2016 around a period of 61
382 months. This result implies that after 1973 the nonlinear phase coupling between modes with periods of approximately
383 30.5 and 61 intensifies., consistent with the ENSO regime shift (Santoso et al., 2013). This intensification is also
384 evident in the Niño 1+2 auto-bicoherence spectrum, though the exact periods associated with the phase-coupled
385 oscillatory modes are more difficult to discern. Nevertheless, a comparison of Figures 4 and 8 reveals that enhanced
386 skewness coincides with stronger auto-bicoherence in the 32- to 64-month period, suggesting that the skewness
387 partially arose from the stronger quadratic phase coupling among modes with periods ranging from 32 to 64 months.
388 The correspondence between auto-bicoherence and time-domain skewness also holds for the Niño 3 and Niño 3.4
389 time series (not shown).

390 The second feature of interest in the Niño 3 and Niño 3.4 auto-bicoherence spectra is the one that emerges
391 around 1995 at a period of 31 months, indicating that the onset of this quadratic phase coupling occurred well after
392 the 1970s regime shift just before the 1997/1998 El Niño event. Thus, the nonlinear character of, say, the 1982/1983
393 El Niño is different from that of both the 1997/1998 and 2015/2016 El Niño events because of the additional quadratic
394 phase coupling between the 15.5- and 31-month modes.

395 Figure 8 also shows that there are other time periods when ENSO behaved nonlinearly, and so the recent
396 nonlinear events may not be unique to recent decades. For example, the auto-bicoherence spectrum of the Niño 3.4
397 time series is associated with enhanced auto-bicoherence around 1875 in the 32- to 128-month period band.

398 To confirm that the nonlinear phase coupling identified in Figure 8 is associated with skewed waveforms, we
399 inspected the corresponding local bi-phase spectra (not shown). It was found that the bi-phase in the 42- to 64-month
400 period band is generally 0° so that the nonlinear phase coupling in that period band contributes to the positive skewness
401 of the 1982/1983, 1997/1998, and 2015/2016 events.

402 **4.4 Nonlinear Coherence between All-India Rainfall and ENSO**

403 The results shown in Figure 9 indicate that the nonlinear wavelet coherence between AIR and the time series
404 for the all four ENSO indices is statistically significant in the 32- to 64-month period band mainly prior to the 1980s.
405 The nonlinear coherence in this period band appears to peak around the 1972/1973 El Niño event, indicating that an
406 increase in positive skewness of ENSO should tend to coincide with enhanced negative skewness of AIR around this
407 time. However, much of the statistically nonlinear coherence is located during the time period when ENSO is more
408 linear than it has been in recent decades (Figure 8) so that the effects of nonlinearities are small regardless of the
409 nonlinear wavelet coherence. In contrast, the auto-bicoherence of the ENSO time series in the 32- to 64-month period
410 band is statistically significant and high after the 1970s (Figure 8) so that the lack of nonlinear coherence after 1980s
411 shown in Figure 9 is expected to impact the time-domain correlation more strongly, much like the theoretical situation
412 shown in Figure 2. Our results are consistent with this theoretical idea because the AIR-Niño 1+2 relationship weakens
413 more than the AIR-Niño 4 relationship after the 1970s (Figure 5), which is expected because the Niño 1+2 index is
414 more nonlinear than the Niño 4 index during this time period. However, unlike the theoretical example shown in
415 Figure 2, the linear coherence between the ENSO time series and AIR also weakens around the 1990s (Figure 8) so
416 that the weakening relationship could be the result of a combination of factors that includes ENSO nonlinearity.

417 The 20-year sliding mean of the ENSO auto-bicoherence, coherence, and nonlinear coherence averaged in
418 the 32 to 64-month period band further highlights the impact of ENSO nonlinearity. As shown in Figure 10a, the
419 sliding mean nonlinear coherence between the Niño 1+2 index and AIR fluctuates less than linear coherence and
420 reaches a clear global maximum around the 1970s before rapidly declining to a global minimum around the late 1990s
421 when the Niño 1+2 index is very nonlinear. As shown in Figure 10a, the Niño 1+2 auto-bicoherence peaks around the
422 same time the August-September AIR-Niño 1+2 index correlation is positive. In fact, the correlation between the
423 sliding September-August AIR-Niño 1+2- correlation time series and the sliding Niño 1+2 auto-bicoherence time
424 series is 0.81, much higher than the correlation with the linear coherence ($r = -0.11$) and nonlinear coherence ($r = -$
425 0.34) time series. These results support the idea that the Niño 1+2 regime shift impacted the weakening time-domain
426 correlation. On the other hand, the correlation between Niño 4 auto-bicoherence and the August-September AIR-Niño
427 4 correlation time series is weak so that changes in the nonlinearity of the Niño 4 index unlikely contributed
428 substantially to changes in the AIR-Niño 4 relationship. Nevertheless, this result agrees with theory that suggests that
429 nonlinearity is only an important contributor when the timeseries is highly nonlinear, which is not the case for the
430 Niño 4 index because of the low auto-bicoherence (Figure 10b). Because the nonlinear coherence between AIR and
431 indices for the Niño 1+2 and Niño 4 is weak (Figure 10), the more pronounced change in the August-September AIR-
432 Niño 1+2 correlation reflects the more intense increase in Niño 1+2 nonlinearity compared to that of the Niño 4 index
433 in recent decades.

434 **4.5. A possible explanation for the ENSO Nonlinearity Impacts**

435 To better understand the association between ENSO nonlinearity and the AIR-ENSO relationship, the global
436 auto-bicoherence spectra associated with the ENSO time series were first computed (Figure 11). Then, the auto-
437 bicoherence of SSTs associated with a few select peaks (p_1, p_2) in Figure 8 were computed at each grid point in the
438 domain bounded by 20°N and 20°S and by 146°E and 80°W . The peaks were selected based on the auto-bicoherence
439 spectra of the Niño 3.4 and Niño 1+2 indices. To select the peaks, local maxima in auto-bicoherence within the
440 statistically significance regions shown in Figure 11 were identified, where points associated with local maxima were
441 chosen because they were associated with the clearest patterns.

442 The spatial structure of global auto-bicoherence corresponding to the peaks in the Niño 3.4 auto-bicoherence
443 spectrum are shown in Figure 12. The auto-bicoherence associated with the pair (31, 31) is greatest across the central
444 equatorial Pacific, with the overall spatial pattern being reminiscent of a central Pacific El Niño (Lee and McPhaden,
445 2010). This result suggests that the phase coupling between the 31-month mode and the 15.5-month mode could be
446 related to the occurrence of central Pacific El Niño events (Section 5). In contrast, the auto-bicoherence pattern
447 associated with the pair (56, 56) is more uniform, with auto-bicoherence slightly greater across the extreme eastern
448 equatorial Pacific than the central equatorial Pacific. This pattern is reminiscent of an eastern Pacific El Niño. Like
449 the pattern corresponding to the pair (31, 31), the auto-bicoherence for the pair (105, 57) tends to be greater across the
450 central equatorial Pacific. Our findings suggest that different nonlinear modes contribute to different ENSO flavors.
451 Although An and Jin (2004) and Burgers and Stephenson (1999) showed that skewness is greatest across the eastern
452 equatorial Pacific, we determined that such a time-domain approach is unable to capture frequency-dependent patterns
453 in nonlinearity.

454 The spatial auto-bicoherence plots associated with the peaks in the Niño 1+2 auto-bicoherence spectrum are
455 shown in Figure 13. The auto-bicoherence associated with the pairs (148, 53) and (148, 105) is strong across the
456 eastern equatorial Pacific but weak across the central equatorial Pacific, suggesting that the quadratic phase coupling
457 between the 148- and 105-month modes and between the 148- and 53-month modes are associated with the skewness
458 of eastern equatorial Pacific SSTs. The pattern associated with the pair (62, 44) is reminiscent of an eastern Pacific El
459 Niño and the auto-bicoherence associated with the pair (88, 88) is relatively weak across the entire equatorial Pacific.
460 A comparison of Figures 12 and 13 shows that there is a tendency for auto-bicoherence to be greater across the eastern
461 equatorial Pacific than the central equatorial Pacific, which is consistent with the results shown in Figure 4 and that
462 of An and Jin (2004) and Burgers and Stephenson (1999) who found that SSTs across the eastern equatorial Pacific
463 are most skewed.

464 5. Discussion/Conclusion

465 The nonlinear nature of ENSO was examined using higher-order wavelet methods. The auto-bicoherence
466 spectra of the four ENSO time series revealed that ENSO skewness arose from the quadratic phase coupling of modes
467 with various periods. The Niño 3.4 time series was found to contain coupling between modes with period 31 and 15.5
468 in addition to coupling between modes with period of 61 months and 30.5 months. The phase coupling between the
469 31 and 15.5 modes was found to be especially strong after 1995, whereas the quadratic phase coupling between the
470 61- and 30.5-month modes was found to intensify after the 1970s. The stronger phase coupling after the 1970s is
471 consistent with how ENSO underwent a regime shift in the 1970s (Santoso et al., 2013), which was marked by an
472 increase in ENSO skewness.

473 The evolution of SSTs across the Niño 4, Niño 3.4, Niño 3, and Niño 1+2 regions was found to be nonlinear,
474 but the degree to which the time series are nonlinear are different. Overall, the Niño 1+2 time series was found to be
475 the most nonlinear, while the Niño 4 index was found to be the most linear. The spatial patterns associated with the
476 nonlinearities depend on the frequency components contributing to the nonlinearities. For example, the quadratic
477 phase coupling between the modes with periods of 31 and 15.5 months was found to be strongest in the central
478 equatorial Pacific and weakest across the eastern equatorial Pacific. This finding suggest that the more frequent
479 occurrence of central Pacific El Niño events in recent decades (Lee and McPhaden, 2010) could be linked to the
480 strengthening of this quadratic phase coupling (Figure 8), which could explain the relationship between ENSO
481 nonlinearity and changes in the ENSO-AIR because central Pacific El Niño events have been shown to be more
482 effective at creating drought-inducing subsidence over India (Kumar et al., 2006).

483 The results from the present and previous studies (Fan et al. 2017) supports the idea that changes in the
484 ENSO-AIR relationship are related to ENSO flavors because ENSO nonlinearity appears to be related to ENSO flavors
485 (Figures 12 and 13), opposing the findings of other work showing that the changes are related to sampling variability
486 or to noise. According to Yun and Timmermann (2018), the changes in the time-domain correlation between All-India
487 summer rainfall (ISMR) and ENSO is consistent with the assumption that ISMR is the sum of the ENSO signal and
488 Gaussian white noise (i.e., $ISMR = ENSO + \text{white noise}$). However, for this hypothesis to hold, the difference $ISMR$
489 $- ENSO$ must be Gaussian white noise. As shown in this study, the nonlinear wavelet coherence between ENSO

490 metrics and AIR is weak so that ENSO – AIR contains periodicities (Figure S2), which means that AIR is not simply
491 a stochastically perturbed ENSO signal, as noise does not contain periodicities. The retention of non-Gaussian noise
492 features was certainly the case for $R(t) - F(t)$ in the example in Section 3.5 because the difference would retained the
493 cosine function with a period of 16.

494 The fact that nonlinear coherence between rainfall and ENSO is determined by linear coherence between
495 ENSO and rainfall at two or three frequencies means that the changing time-domain correlation could be more fully
496 understood by determining why linear coherence changes at the frequencies that contribute to ENSO skewness. Such
497 an analysis could provide a more mechanistic perspective than the theoretical perspective adopted in this study. A
498 preliminary analysis showed that enhanced linear coherence between the North Atlantic Oscillation index and AIR
499 after 1995 in the 16- to 64-month period band associated with ENSO nonlinearity. This result suggests that conditions
500 across the North Atlantic (Kakade, 2000, Bhatla, 2016) could influence the nonlinear coherence between ENSO and
501 AIR and thus the corresponding time-domain correlation.

502 The tools used and developed in this study may have important applications in understanding how forecasting
503 systems replicate Indian rainfall and its associated teleconnections. These methods, for example, could determine if
504 forecasting systems can reproduce nonlinear characteristics of climate time series. As such, a R software package has
505 been developed to implement these methods (available at: <http://justinschulte.com/wavelets/advbiwavelet.html>; last
506 access: 22 November 2019). These methods could provide new directions for improving current forecasting systems
507 and ultimately predictions of Indian rainfall.

508

509

510

511 **Appendix A**

512 The first step (STEP 1) in assessing the cumulative-area significance of a point was the calculation of the N
513 = 12 sets

$$514 P_{pw}^i = \{(b, a): \rho_{pw}(b, a) < \alpha_i\}, \quad (A1)$$

515 where each set is the subset of the wavelet domain consisting of points whose wavelet quantities are point-wise
516 statistically significant at the α_i significance level (i.e. the point-wise test p-value, ρ_{pw} , is less than α_i). In this paper,
517 $\alpha_1 = 0.02$, $\alpha_{12} = 0.18$, and $\alpha_{i+1} - \alpha_i = 0.02$. In the second step (STEP 2), a geometric pathway about x was computed,
518 where a geometric pathway is a nested sequence

$$519 P_1^x \subseteq P_2^x \subseteq \dots \subseteq P_N^x \quad (A2)$$

520 such that the

$$521 P_i^x = \{(b, a): (b, a) \in P_{pw}^i, (b, a) \sim x\} \quad (A3)$$

522 are path-components of P_{pw}^i containing x . The equivalence relation \sim on P_{pw}^i makes two points in P_{pw}^i equivalent if
523 they can be connected by a continuous path in P_{pw}^i . The third step (STEP 3) involved the calculation of the normalized
524 area corresponding to P_i^x . The normalized area is defined as patch area divided by the square of mean scale coordinate
525 of the patch, where A_i^x was assumed to be 0 if $P_i^x = \emptyset$ or $P_i^x = \{x\}$. The critical area A_i^{crit} was obtained by computing
526 the $(1 - \alpha_c)$ th percentile of the null distribution of normalized areas corresponding to the significance level α_i , where
527 α_c is the significance level of the cumulative area-wise test. The null distributions were constructed by generating
528 1000 patches at the α_i significance level under the null hypothesis of red noise. The final step (Step 4) was to compute

$$529 r^x = \frac{1}{N} \sum_{j=1}^N \lambda_j^x, \quad (A4)$$

530 where $\lambda_i^x = 2$ if $P_i^x / A_i^{crit} > 1$ and $\lambda_i^x = 0$ if $P_i^x / A_i^{crit} \leq 1$. The wavelet quantity at the point x was deemed statistically
531 significant at the α_c cumulative area-wise level if $r^x > 1$.

532

533 **Appendix B**

534 For $p > 1$, the $(p+1)$ -th order poly spectrum of a time series X is given by

535
$$B_n^X(s_1, s_2, \dots, s_p) = \widehat{W}_n^X(s_{p+1}) \left(\prod_{k=1}^p W_n^X(s_k) \right) \quad (\text{B1})$$

536 where

537
$$\frac{1}{s_{p+1}} = \sum_{k=1}^p \frac{1}{s_k} \quad (\text{B2})$$

538 The third-order poly spectrum is the bi-spectrum, and the fourth-order poly spectrum is the tri-spectrum (Collis et al.,
539 1998), which identifies the frequency components contributing to kurtosis. The $(p+1)$ -th order coherence between two
540 time series is given as

541
$$R_n^2(s) = \frac{|s_{smooth}^{-1} B_n^{XY}(s_1, s_2, \dots, s_p)|^2}{s(s_{smooth}^{-1} |B_n^X(s_1, s_2, \dots, s_p)|^2) s(s_{smooth}^{-1} |B_n^Y(s_1, s_2, \dots, s_p)|^2)}, \quad (\text{B3})$$

542 where $B_n^{XY}(s_1, s_2, \dots, s_p)$ is the $(p+1)$ -th-order cross-spectrum given by

543
$$B_n^{XY}(s_1, s_2, \dots, s_p) = B_n^X(s_1, s_2, \dots, s_p) \widehat{B}_n^Y(s_1, s_2, \dots, s_p). \quad (\text{B4})$$

544 When $p = 2$, Eq. (B3), measures the local cross-correlation between skewness, and when $p = 3$ the equation
545 measures the local cross-correlation between kurtosis.

745

746 Figure 5. 20-year sliding correlation between anomalies for June-September AIR and the time series for the June-
747 September Niño 1+2 and Niño 4 indices. (c) Same as (b) but for the August-September season.

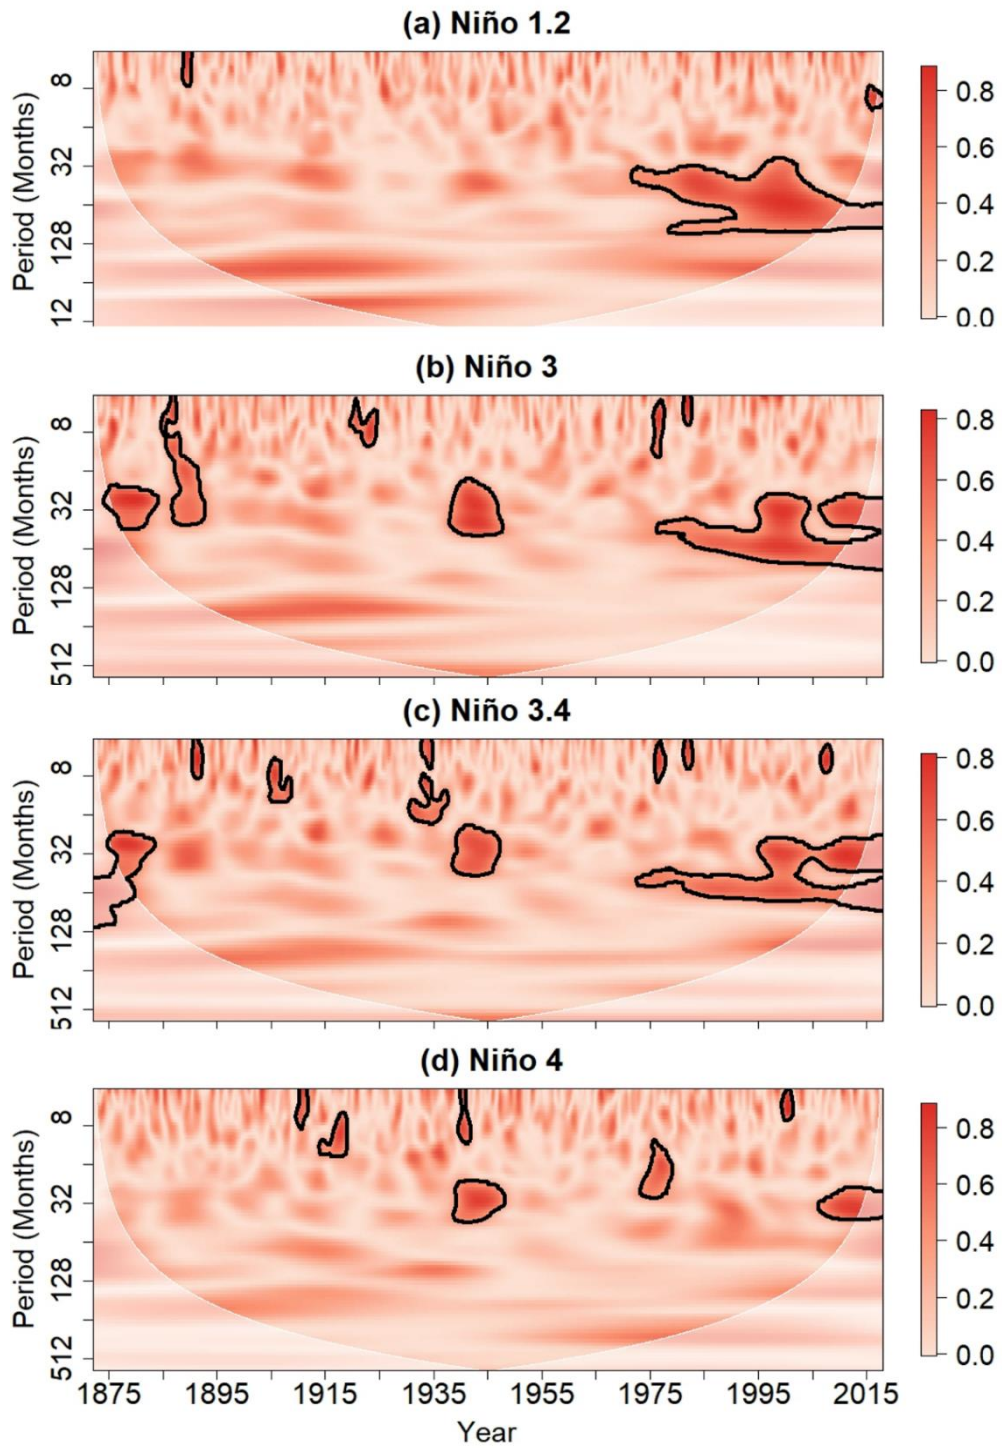

749

750 Figure 6. Wavelet Power spectrum of the (a) Niño 1+2, (b) Niño 3, (c) Niño 3.4, and (d) Niño 4 indices. Contours
 751 enclose regions of 5% cumulative area-wise significance. Light-shaded region represents the cone of influence,
 752 which is the region where edge effects are non-negligible.

753
 754 Figure 7. Wavelet coherence spectrum between AIR and time series for the (a) Niño 1+2 and (b) Niño 4 indices.
 755 Contours enclose regions of 5% cumulative area-wise significance. Light-shaded region represents the cone of
 756 influence, which is the region where edge effects are non-negligible.
 757

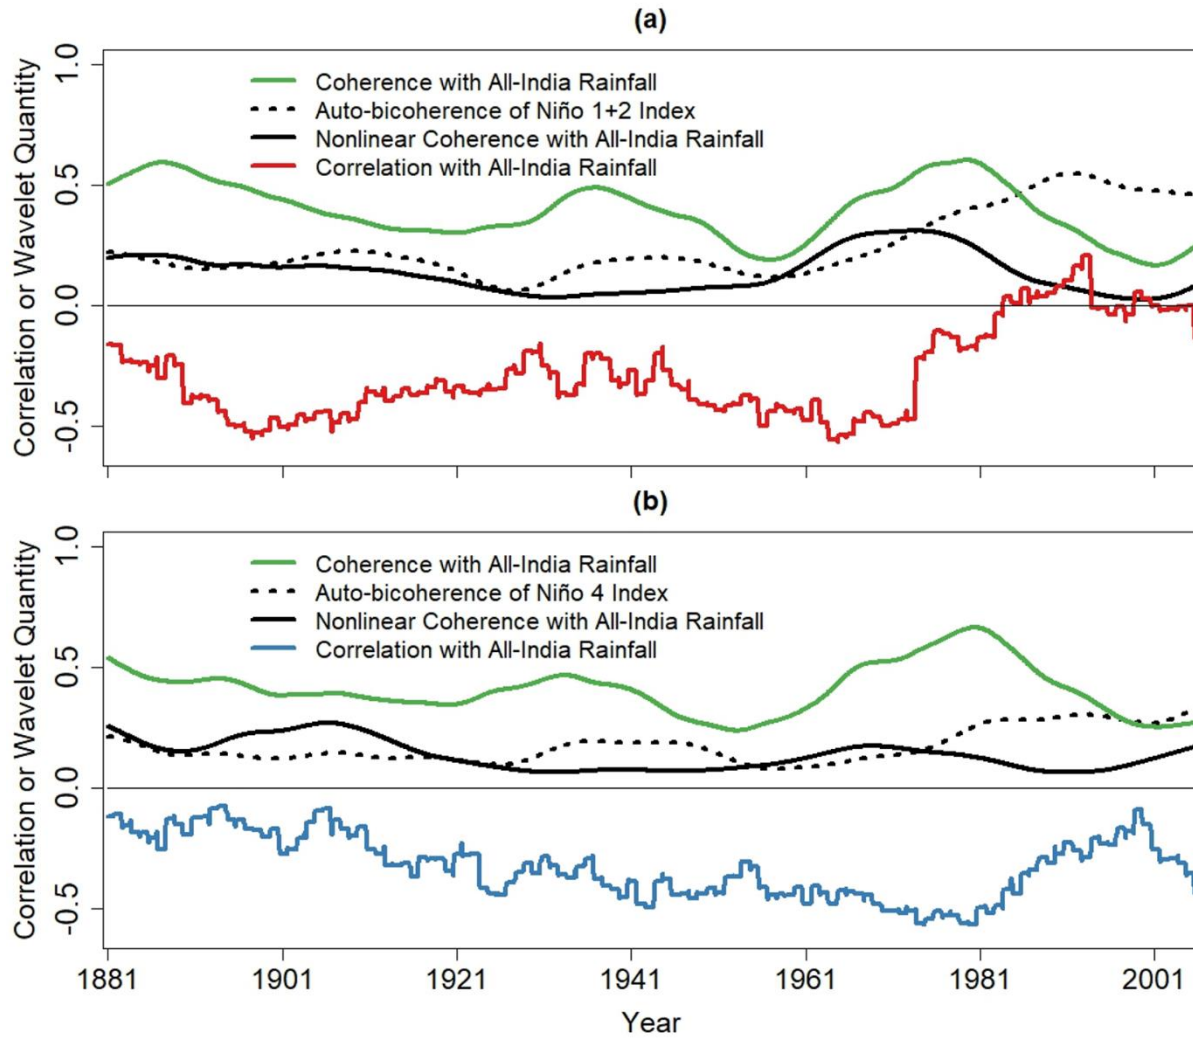

758
 759 Figure 8. Local auto-bicoherence spectra of the (a) Niño 1+2, (b) Niño 3, (c) Niño 3.4, and (d) Niño 4 indices.
 760 Contours enclose regions of 5% cumulative area-wise significance and the light shading represents the cone of
 761 influence.

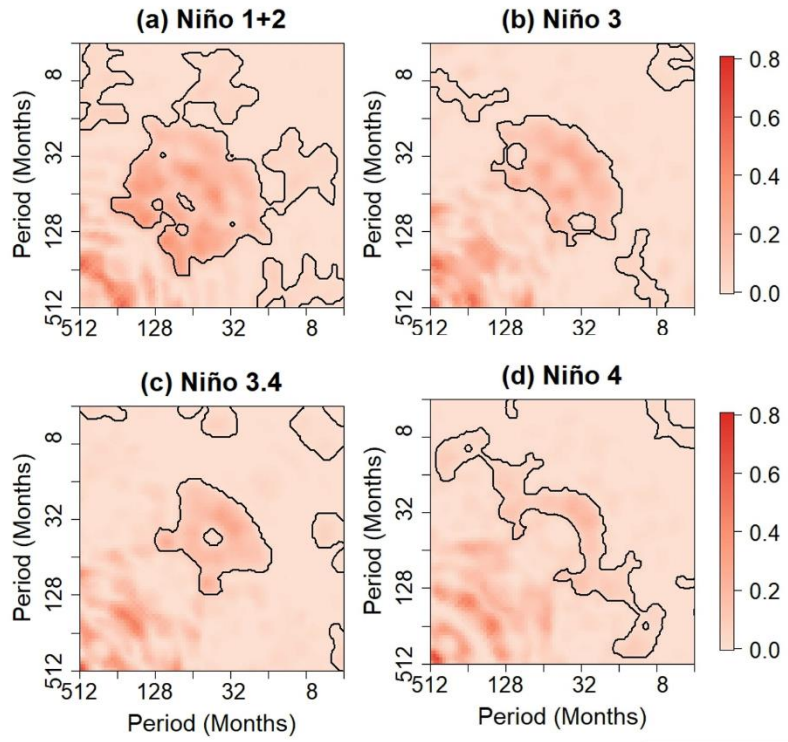

762
 763 Figure 9. Nonlinear wavelet coherence between the full AIR series and full times series for the (a) Niño 1+2, (b) Niño
 764 3, (c) Niño 3.4, and (d) Niño 4 indices. Contours enclose regions of 5% cumulative area-wise significance and light
 765 shading represents the cone of influence.

766

767 Figure 10. (a) 20-year sliding mean time series of the linear wavelet coherence between AIR and the Niño 1+2 index,
 768 the auto-bicoherence of the Niño 1+2 index, and the nonlinear coherence between the Niño 1+2 index and AIR after
 769 they have been averaged in the period band of 16 to 64 months. Red curve is the 20-year sliding correlation between
 770 the August-September Niño 1+2 index and AIR. (b) The same as (a) but for the Niño 4 index. Blue curve is the 20-
 771 year sliding correlation between the August-September Niño 4 Index and AIR.
 772

773

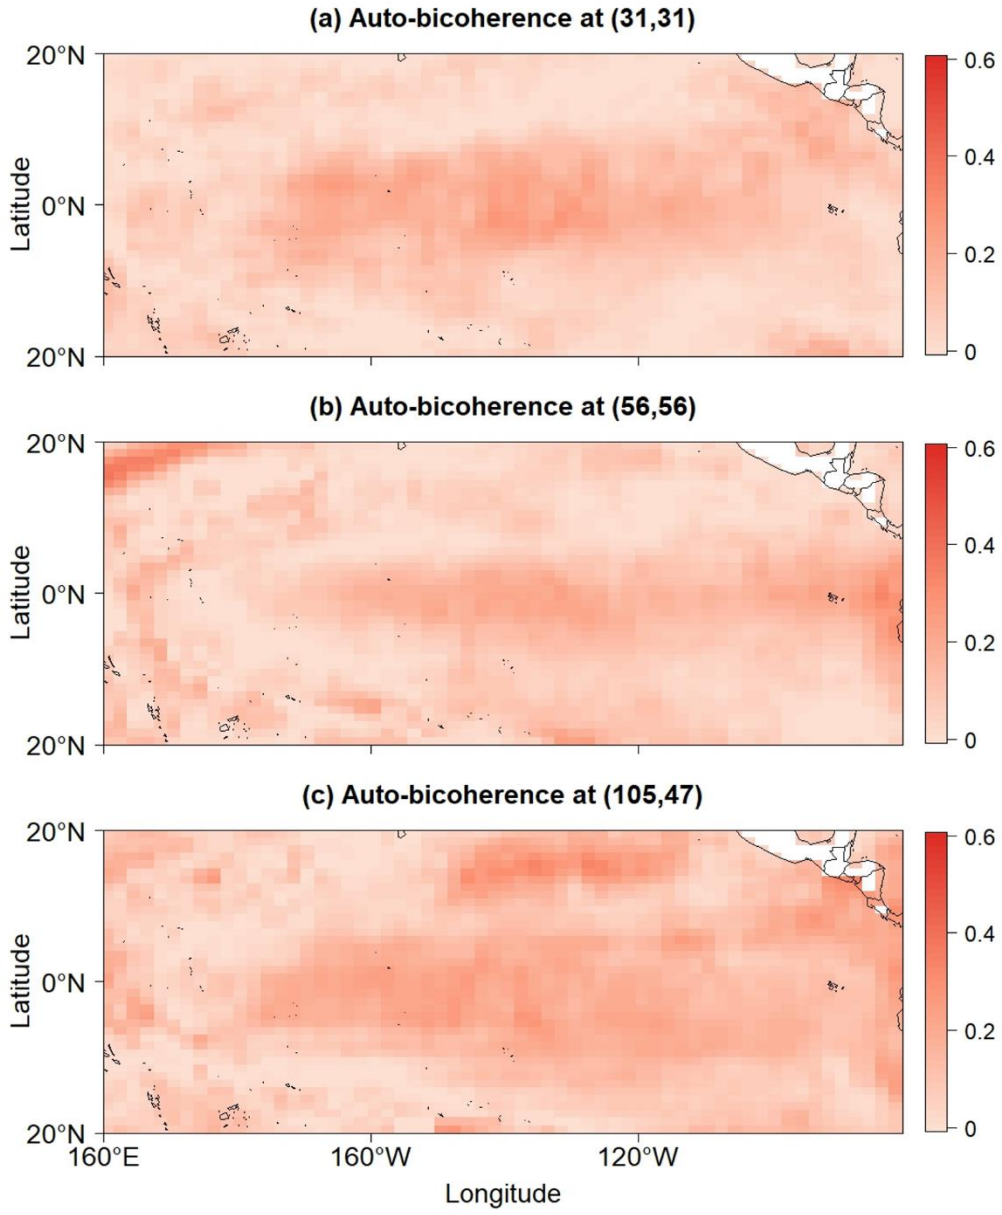

774
775

776 Figure 11. Global auto-bicoherence spectra of the (a) Niño 1+2, (b) Niño 3, (c) Niño 3.4, and (d) Niño 4 indices.
777 Contours enclose regions of 5% cumulative area-wise significance.

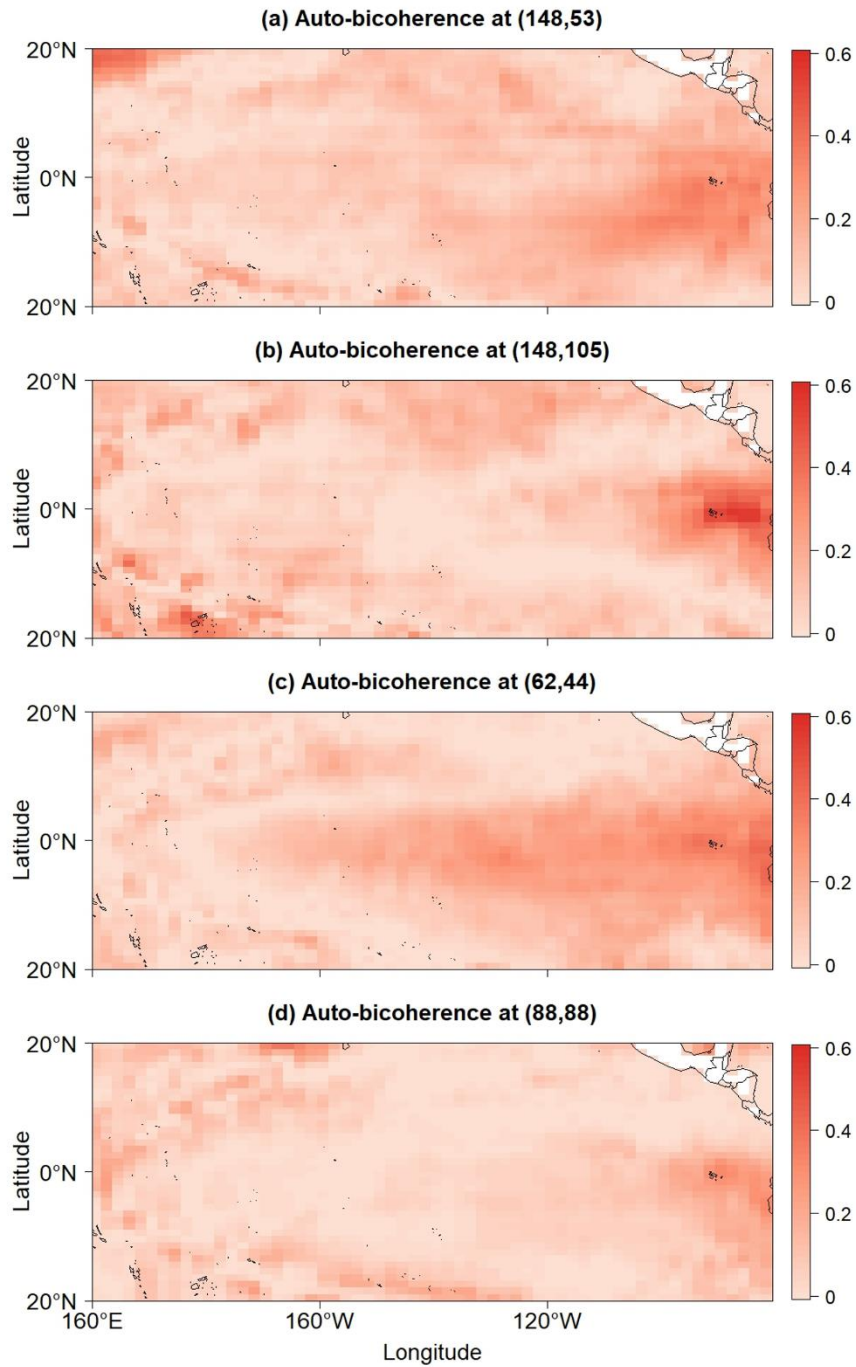

778

779

780

781 Figure 12. Global auto-bicoherence corresponding to the pairs (a) (31, 31), (b) (56, 56), and (c) (105, 47) [months].

782

783 Figure 13. Global auto-bicoherence corresponding to the pairs (a) (158, 43), (b) (148, 105), (c) (62, 44), and (d)

784

(88,88) [months].

785

786 Table 1. Wavelet quantities and the relationships they measure.

Wavelet Quantity	Quantified Relationship
Linear Coherence	Cross-correlation between the variance of two time series at a Fourier period
Global Auto-bicoherence	Time-averaged quadratic phase coupling among two or three linear modes
Local Auto-bicoherence	Quadratic phase coupling among two or three linear modes at a time point
Nonlinear Coherence	Cross-correlation between the skewness of nonlinear modes
