A 1962 recession hydrograph for Big Spring, Missouri, USA

This follow-up will illustrate a comparison of the universal logarithmic and the new NISR transformation as represented, in SC1, by Equations (1) and (2).

Figure 2 summarizes result of a new recession flow analysis for year 1962 for Big Spring near Van Buren, in Missouri, a regional-scale limestone karst having a drainage

area of 1500 km².

The graph shows a long recession hydrograph from May to August of 1962 (Florea and Vacher, 2006, Figure 2C). The recession literally started one day after the last of the major peaks and ended at the start of the next noticeably uptick. It also includes the log and NISR transformation of the observed flow.

In their absolute value, from untransformed, to log-, and finally NISR-transformed recession hydrograph, the correlation coefficient R improves incrementally; and the recession slope flattens successively by one order of magnitude.
