20 **Abstract:**

21       Reliable modeling of carbon and water fluxes is essential for understanding the terrestrial carbon  
22 and water cycles and informing policy strategies aimed at constraining carbon emissions and improving  
23 water use efficiency. We designed an assimilation framework (LPJ-Vegetation and soil moisture Joint  
24 Assimilation, or LPJ-VSJA) to improve gross primary production (GPP) and evapotranspiration (ET)  
25 estimates globally. The integrated model, LPJ-PM (LPJ-PT-JPL<sub>SM</sub> Model) as the underlying model, was  
26 coupled from the Lund-Potsdam-Jena Dynamic Global Vegetation Model (LPJ-DGVM version 3.01) and  
27 a hydrology module (i.e., the updated Priestley–Taylor Jet Propulsion Laboratory model, PT-JPL<sub>SM</sub>).  
28 Satellite-based soil moisture products derived from the Soil Moisture and Ocean Salinity (SMOS) and  
29 Soil Moisture Active and Passive (SMAP) and leaf area index (LAI) from the global Land and Ground  
30 satellite (GLASS) product were assimilated into LPJ-PM to improve GPP and ET simulations using a  
31 Proper Orthogonal Decomposition-based ensemble four-dimensional variational assimilation method  
32 (PODEn4DVar). The joint assimilation framework LPJ-VSJA achieved the best model performance (with  
33 an  $R^2$  of 0.91 and 0.81 and an ubRMSD reduced by 40.3% and 29.9% for GPP and ET, respectively,  
34 compared with those of LPJ-DGVM at the monthly scale). The GPP and ET resulting from the  
35 assimilation ~~assimilated GPP and ET~~ demonstrated a better performance in the arid and semi-arid regions  
36 (GPP:  $R^2=0.73$ , ubRMSD=1.05 g C m<sup>-2</sup> d<sup>-1</sup>; ET:  $R^2=0.73$ , ubRMSD= 0.61 mm d<sup>-1</sup>) than in the humid and  
37 sub-dry humid regions (GPP:  $R^2=0.61$ , ubRMSD=1.23 g C m<sup>-2</sup> d<sup>-1</sup>; ET:  $R^2=0.66$ ; ubRMSD=0.67 mm d<sup>-1</sup>)

38 <sup>1</sup>). The ET simulated by LPJ-PM that assimilated SMAP or SMOS had a slight difference, and the SMAP  
39 soil moisture data performed better than that of SMOS data. Our global simulation modeled by LPJ-VSJA  
40 was compared with several global GPP and ET products (e.g., GLASS GPP, GOSIF GPP, GLDAS ET,  
41 GLEAM ET) using the triple collocation (TC) method. Our products, especially ET, exhibited advantages  
42 in the overall error distribution (estimated error ( $\mu$ ): 3.4 mm month<sup>-1</sup>; estimated standard deviation of  $\mu$ :  
43 1.91 mm month<sup>-1</sup>). Our research showed that the assimilation of multiple datasets could reduce model  
44 uncertainties, while the model performance differed across regions and plant functional types. Our  
45 assimilation framework (LPJ-VSJA) can improve the model simulation performance of daily GPP and  
46 ET globally, especially in water-limited regions.

50 **1. Introduction**

51 Gross primary production (GPP) and evapotranspiration (ET) are essential components of the carbon  
52 and water cycles. Carbon and water fluxes are inherently coupled on multiple spatial and temporal scales  
53 (Law et al. 2002; Sun et al. 2019; Waring and Running 2010). Terrestrial biosphere models are the most  
54 sophisticated approach for providing a relatively detailed description of such interdependent relationships  
55 regarding water and carbon fluxes and understanding the response of terrestrial ecosystems to changes in  
56 atmospheric CO<sub>2</sub> and climate (Kaminski et al. 2017). The dynamic global vegetation tionle models (DGVMs)

57 are process-based dynamic terrestrial biosphere models, which can simulate water, carbon, and  
58 energy material exchange between vegetation and the atmosphere under different conditions accounting  
59 for different conditions from the perspective of vegetation physiological processes, and are widely used  
60 to estimate carbon and water fluxes of terrestrial vegetation. However, there are still large uncertainties  
61 in carbon and water flux estimates at regional to global scales. Both diagnostic and prognostic models  
62 show substantial differences in the magnitude and spatiotemporal patterns of GPP and ET. For example,  
63 the global annual GPP estimates exhibited a large range (130–169 Pg C yr<sup>-1</sup>) among 16 process-based  
64 terrestrial biosphere models (Anav et al. 2015). The global ET ranged from 70,000 to 75,000 km<sup>3</sup> yr<sup>-1</sup>,  
65 and the uncertainty of regional or global ET estimates was up to 50% of the annual mean ET value,  
66 especially in the semi-arid regions (Miralles et al. 2016). These uncertainties mainly arise from the forcing  
67 datasets, simplification of mechanisms or imperfect assumptions in processes, and uncertain parameters  
68 in the processed models and assimilation methods (Xiao et al. 2019).

69 In the last two decades, remote sensing products have been assimilated into DGVMs to reduce the  
70 uncertainty in modeled carbon and water fluxes (MacBean et al. 2016; Scholze et al. (2017); Exbrayat  
71 et al. (2019)). Data assimilation (DA) is an effective approach to reduce uncertainties in terrestrial  
72 biosphere models by integrating satellite products with models to constrain related parameters or state  
73 variables. A DA system contains four main components: a set of observations, an observation operator,  
74 an underlying model, and an assimilation method. The assimilation method considers the errors from both  
75 models and observations, and reduces model uncertainties by minimizing a cost function. The Ensemble  
76 Kalman Filter (EnKF) has been widely applied in land surface process models for parameter optimization,

77 which significantly improve simulations by periodically updating state variables (e.g., LAI and soil  
78 moisture) using remote sensing data without altering the model structure ( Rahman et al. 2021; [Bonan et  
79 al. 2020; Xu et al. 2021](#)). Yet, the EnKF relies on the instantaneous observations to update the state  
80 variable at the current time, and gives the predicted value at the next time based on the forward integration  
81 of the updated state variable. The four-dimensional variational method (4DVar) assimilation method can  
82 obtain the dynamic balance of the estimation in the time window when it is applied to the long-series  
83 forecast model ([Bateni et al. 2014; and Xu et al. 2019](#)). In particular, the Proper Orthogonal  
84 Decomposition (POD)-based ensemble 4DVAR assimilation method (referred to as PODe4DVar) (Tian  
85 and Feng 2015) requires relatively less computation and can simultaneously assimilate the observations  
86 at different time intervals. Meanwhile, it maintains the structural information of the four-dimensional  
87 space. This method has a satisfactory performance in land DA for carbon and water variables (Tian et al.  
88 2009; Tian et al. 2010) and can better estimate GPP and ET than EnKF (Ma et al. 2017).

89 Multiple sources of remote sensing data streams have been used to constrain models for assimilation.  
90 As a critical biophysical parameter of the land, leaf area index (LAI) is closely related to many land  
91 processes, such as photosynthesis, respiration, precipitation interception, ET, and surface energy  
92 exchange (Fang et al. 2019). [LAI has a lot of impact on](#)~~LAI is highly sensitive to~~ the simulation of carbon  
93 and water fluxes (Liu et al. 2018), and accurate LAI estimates can improve the simulations of the carbon  
94 and water fluxes (Bonan et al. 2014;; Mu et al. 2007). [He et al. \(2021\)- assimilated land surface  
95 temperature and LAI observations into the 4DVar framework and improved](#)~~s~~ [ET and GPP estimates](#). Soil  
96 moisture is a major driving factor affecting vegetation production in arid ecosystems, especially, in semi-

97 arid areas (Liu et al. 2020). Introducing surface soil moisture (SSM) into the model can significantly  
98 improve GPP and ET simulation, particularly in water-limited areas (He et al. 2017; Li et al. 2020).

99 The advancement of earth observation, machine learning, inversion algorithms, and computer  
100 technology has improved the accuracy of global LAI products and boosted model-data fusion studies  
101 (Fang et al. 2019; Kganyago et al. 2020; Xiao et al. 2017). The Advanced Very High-Resolution  
102 Radiometer (AVHRR) generates global LAI products with the longest historic record (since the early  
103 1980s). The GLASS LAI product has been verified to have a better accuracy than that of MODIS and  
104 CYCLOPES and is more temporally continuous and spatially complete (Xiao et al. 2013). Several recent  
105 studies showed that the assimilation of GLASS LAI into DGVMs enhanced the performance of the  
106 models in simulating carbon cycling (e.g., GPP, Net Ecosystem Exchange (NEE)) and hydrological (e.g.,  
107 ET, SM) processes (Ling et al. 2019; Ma et al. 2017; Yan et al. 2016).

108 Microwave remote sensors are considered effective tools for measuring SM globally (Petropoulos et  
109 al. 2015). For example, ~~surface SM~~ SSM products have been derived from the Soil Moisture and Ocean  
110 Salinity (SMOS) and Soil Moisture Active and Passive (SMAP) satellites equipped with an L-band  
111 microwave instrument. The products from these satellites have been evaluated against in-situ observations  
112 and other SSM products and overall have high accuracy (Burgin et al. 2017; Cui et al. 2018). Additionally,  
113 the SMAP performs better than SMOS and other SSM products (e.g., Advanced Scatterometer (ASCAT),  
114 Advanced Microwave Scanning Radiometer 2 (AMSR2)) with an overall lower error and a higher  
115 correlation based on the verification with in-situ SSM data from 231 sites (Cui et al. 2018; Kim et al.  
116 2018). The assimilation of SMAP data can improve the simulation accuracy of carbon and water fluxes

117 (He et al. 2017; Li et al. 2020) and hydrological variables (surface soil moisture, root-~~zone~~-zone soil  
118 moisture (RZSM), and streamflow) (Blyverket et al. 2019; Koster et al. 2018; Reichle et al. 2017). In  
119 addition, the assimilation of SMAP data performed slightly better than that of SMOS and ESA CCI data  
120 (Blyverket et al. 2019).

121 In the nonlinear model or nonlinear observation operator, only simultaneous assimilation makes  
122 optimal use of observations (MacBean et al. 2016). Therefore, a joint assimilation of ~~soil moisture~~-SM  
123 and LAI can make full use of the two variables. From site (Albergel et al. (2010);Rüdiger et al. (2010);  
124 Wu et al.,2018) to regional assimilation (Ines et al. (2013)), many studies ~~have proposed~~showed that joint  
125 assimilation of vegetation parameters and ~~soil moisture~~SM is a potential improvement in modelingcan  
126 improve the simulation of the carbon- and water cycles. ~~For instance, joint assimilation of soil moisture~~  
127 ~~and leaf area index can improve the accuracy of crop yield estimation (Xie et al.,2018; Pan et al.,2019),~~  
128 Over small regions and at high spatial resolution, Xie et al. (2018) and Pan et al. (2019) showed that the  
129 joint assimilation of soil moistureSM and leaf area indexLAI can improved the accuracy of crop yield  
130 estimation using high-resolution satellites products from Sentinel-1 and -2, with small region and high  
131 ~~spatial resolution, which adopting observation data from stations or high resolution satellites (e.g.~~  
132 ~~Sentinel 1 and 2).~~ At a large regional scale, Bonan et al. (2020) assimilated LAI and SSM together into  
133 the Interactions between Soil, Biosphere and Atmosphere (ISBA) land model and improved the modeled  
134 GPP, ET, and runoff in the Mediterranean region. Rahman et al. (2022) jointly assimilates GLASS LAI  
135 and SMAP soil moisture to improve water and carbon flux simulations within the Noah-MP model over  
136 the Continental United StatesCONUS domain. Albergel et al.(2020) jointly assimilates the ASCAT soil

137 moisture index (SMI) and LAI GEOV1 into ISBA (~~Interaction between Soil Biosphere and Atmosphere~~)  
138 ~~surface model~~ through the Global Offline Land Data assimilation system LDAS-Monde ~~LDAS Model~~ to  
139 monitor extreme events such as drought and Heatwave events. In conclusion, Kalman Filter and its variant  
140 methods are mostly used to implement ~~are mostly used~~ joint assimilation methods at regional scale, which  
141 requires many kinds of observation data and their accuracy directly affects the assimilation performance.

142 This study stems from the researches discussed above and further explored the potential of jointly  
143 assimilating ~~joint assimilating~~ satellite LAI and soil moisture products globally. Specifically, it was the  
144 first time that an updated LPJ-DGVM model was used to jointly assimilate GLASS LAI and SMAP soil  
145 moisture for simulating global water and carbon fluxes. The latest global soil moisture datasets (SMOS  
146 and SMAP) were used, and the assimilation performance of these two observations was analyzed. Since  
147 previous work showed the importance of surface soil moisture in the semi-arid and arid areas, one of the  
148 specific objectives of our study is to compare the assimilation effect in the humid and arid areas and  
149 improve the understanding of the effect of surface soil moisture on vegetation activity in wet and dry  
150 zones. In addition, compared with the assimilation methods in previous studies (mostly using Kalman  
151 Filter variants), the POD-En4DVar method is used, which greatly improves the computational efficiency.

## 152 **2. LPJ-VSJA framework and assimilation strategy**

### 153 *2.1. Coupled- model (LPJ-PM) for assimilation*

154 In this study, a coupled terrestrial biosphere model, LPJ-PM, was used to simulate daily GPP and  
155 ET by assimilating satellite-derived LAI and SSM. The LPJ-PM is coupled from LPJ-DGVM and PT-

156 JPL<sub>SM</sub>. The original input data in PT-JPL<sub>SM</sub> were all inherited from LPJ-DGVM, with the exception of  
 157 relative humidity (RH) and surface soil moisture (SMOS and SMAP), including the initial LAI calculated  
 158 by the LPJ-DGVM or assimilated LAI obtained through the LAI assimilation scheme, canopy height, and  
 159 the fraction of absorbed photosynthetic effective radiation (fAPAR). The detailed processes of the LPJ-  
 160 PM have been described in Li et al. (2020), and the flow chart for the coupling is shown in Figure 1.

162

### 163 2.1.1 LPJ-DGVM

164 The LPJ-DGVM is a process-oriented dynamic model, which considers mutual interaction of carbon  
165 and water cycling and is designed to simulate vegetation distribution and carbon, soil and atmosphere  
166 fluxes (Sitch et al. 2003). For each plant functional type (PFT), the GPP is calculated by implementing  
167 coupled photosynthesis and water balance

168 The canopy GPP is updated daily:

$$169 \quad GPP = \frac{(J_E + J_C - \sqrt{(J_E + J_C)^2 - 4\theta J_E J_C})}{2\theta} \quad (2.1)$$

170 where  $J_C$  is the Rubisco limiting rate of photosynthesis,  $J_E$  is the light limiting rate of photosynthesis, and  
171 the empirical parameter  $\theta$  represents the common limiting effect between the two terms.  $J_E$  is related to  
172 APAR (absorbed photosynthetic radiation, product of FPAR and PAR), while  $J_C$  is related to  $V_{cmax}$   
173 (canopy maximum carboxylation capacity,  $\mu \text{ mol CO}_2/\text{m}^2/\text{s}$ ):

$$174 \quad J_E = C_1 APAR \quad (2.2)$$

$$175 \quad J_C = C_2 V_{Cmax} \quad (2.3)$$

176 where  $C_1$  and  $C_2$  are determined by a variety of photosynthetic parameters and the intercellular partial  
177 pressure of  $CO_2$ , which is related to atmospheric  $CO_2$  content and further altered by leaf stomatal  
178 conductance (Sitch et al. 2003). APAR and FPAR are directly related to LAI.

179 In the water cycle module, ET is calculated as the minimum of a plant- and soil-limited supply  
180 function ( $E_{supply}$ ) and the atmospheric demand ( $E_{demand}$ ) (Haxeltine and Prentice 1996; Sitch et al.  
181 2003). The soil structure is simplified to a “two-layer bucket” model (the top soil layer at a 0-50 cm depth  
182 and the bottom layer at a 50-100 cm depth) .

$$183 \quad E_s = E_p \times W_{r_{20}} \times (1 - fv) \quad (2.4)$$

184 In this module, it is assumed that the soil layer above 20 cm produces water through evaporation,  
185 and  $W_{r_{20}}$  is the relative water content of the soil above 20 cm, which is used as the only soil water limit  
186 for calculating vegetation transpiration and soil evaporation. In the evapotranspiration estimation, the  
187 over-simplification of soil structure and soil water limitation lead to a large error (Sitch et al. 2003), while  
188 LPJ-DGVM cannot directly assimilate surface soil water due to the limitation of soil layer stratification  
189 , and therefore, the satellite-derived [surface SMSSM](#) cannot be assimilated into LPJ-DGVM directly. The  
190 oversimplified soil structure and single soil moisture limitation inevitably lead to sizeable uncertainty in  
191 ET simulation. Additionally, the monthly input caused a daily variation of the modeled SM, which was  
192 also not transmitted to the calculation of GPP and ET. Thus, the updated PT-JPL model (hereafter referred  
193 to as PT-JPL<sub>SM</sub>) was coupled with LPJ-DGVM and the model structure was modified so that [surface](#)  
194 [SMSSM](#) can be directly assimilated into the coupled model at the daily time step.

## 2.1.2 PT-JPL<sub>SM</sub>

In PT-JPL<sub>SM</sub>, three ET components are modelled: soil evaporation (E), vegetation transpiration (T), and leaf evaporation (I). The PT-JPL<sub>SM</sub> introduced a constraint (0–1, C<sub>RSM</sub>) of surface-SM for T and E, which was used to avoid the implicit soil water control (represented by f<sub>SM</sub>=RH<sup>VPD</sup>) in the PT-JPL model.

Vegetation transpiration:

$$C_{RSM} = (1 - RH^{4(1-VWC)(1-RH)})C_{SM} + (RH^{4(1-VWC)(1-RH)})C_{TRSM}$$

$$C_{RSM} = (1 - RH^{4(1-VWC)(1-RH)})C_{SM} + (RH^{4(1-VWC)(1-RH)})C_{TRSM} \quad (2.5)$$

$$C_{TRSM} = 1 - \left( \frac{w_{CR} - w_{obs}}{w_{CR} - w_{pwp\_CH}} \right)^{\sqrt{CH}} \quad C_{TRSM} = 1 - \left( \frac{w_{CR} - w_{obs}}{w_{CR} - w_{pwp\_CH}} \right)^{\sqrt{CH}},$$

$$(2.6)$$

where w<sub>obs</sub> is the SMAP SSM, w<sub>pwp</sub> is the water content at the wilting point, and ~~w<sub>fc</sub>~~-VWC is ~~the~~ volumetric water content ~~water content at field capacity, which is determined by the properties of the soil.~~ W<sub>CR</sub> is a crucial parameter in characterizing the extent of SM restriction on ET; w<sub>pwp\_CH</sub> is the canopy height (CH) adjusted surface soil moisture wilting point and is related to the potential of roots capturing water from deeper sources to limit the transpiration rate and characterize the SM availability (Purdy et al., 2018; Evensen 2003; Serraj et al., 1999). The specific formula is given in Purdy et al. (2018).

Soil evaporation:

$$C_{\text{RSM}} = \frac{W_{\text{obs}} - W_{\text{pwp}}}{W_{\text{fc}} - W_{\text{pwp}}} \quad (2.7)$$

211

212

213

214

215

The proportion of available water limits the soil evapotranspiration to the maximum available water. This scalar was formulated to represent the relatively accurate extractable water content for the vegetation, determined by soil properties and the water available for evaporation, which is estimated via surface water constraints.

216

217

218

219

220

The SMAP ~~SSM as surface SM data~~ was applied to model global ET using PT-JPL<sub>SM</sub> and the results demonstrated the largest improvements for ET estimates in dry regions (Purdy et al. 2018). Due to the limitation of soil stratification in LPJ-DGVM, the model was coupled with an updated remote-sensing ET algorithm in the PT-JPL<sub>SM</sub> that could better simulate ET in water-limited regions than in humid regions (Purdy et al. 2018).

221

## 2.2. Assimilation scheme and experiment procedure

222

223

224

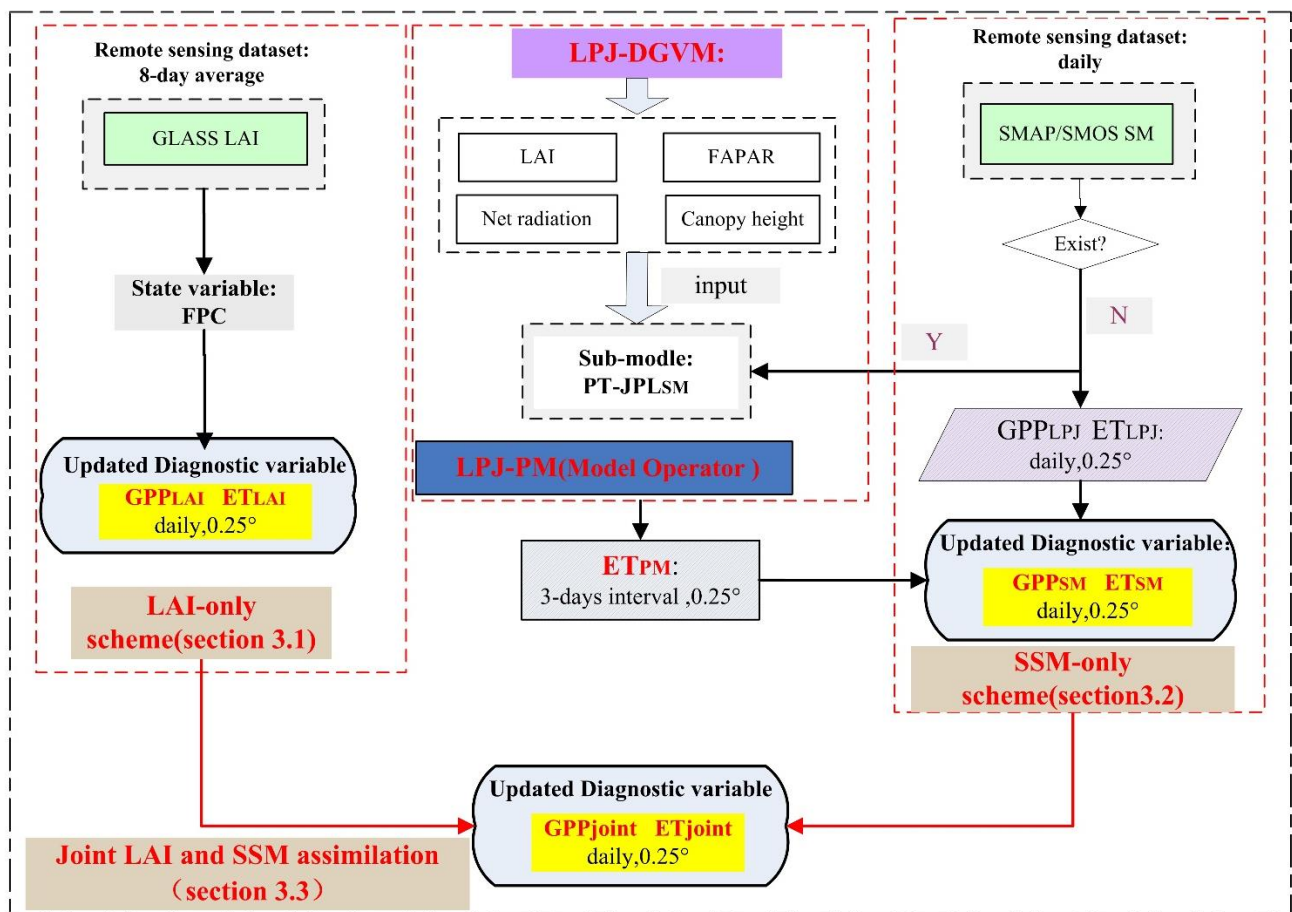

225

226

To improve the prediction capability of LPJ-PM, we designed three assimilation schemes: assimilating LAI ~~only~~ only (~~scheme 1~~ LAI-only, **output: ET<sub>LAI</sub>, GPP<sub>LAI</sub>**), assimilating SSM only (~~SSM-only~~ scheme 2, **output: GPP<sub>SM</sub>, ET<sub>SM</sub>**), and joint assimilation of LAI and SSM (Joint LAI and SSM assimilation ~~scheme 3~~, **output: ET<sub>joint</sub>, GPP<sub>co</sub>, GPP<sub>joint</sub>**), i.e., LPJ-VSJA framework) to test the assimilation performance for simulating GPP and ET.

227 The proposed LPJ-VSJA framework consists of four main components: the model operator (the LPJ-  
 228 PM), the observation operator (to establish the relation between the assimilation variable and the observed  
 229 variable), the observation series (GLASS LAI and SMOS or SMAP products), and the assimilation  
 230 algorithm (POD4DVar). With the surface soil moisture constraint in the PT-JPLSM, the LPJ-VSJA  
 231 corrects the output fluxes (GPP and ET in this study).

### LPJ-VSJA assimilation system

232

233 **Figure 1. Flowchart of the LPJ-VSJA assimilation scheme: three assimilation schemes and the coupled**  
234 **model: LPJ-PM<sub>r</sub> (adapted from Li et al., 2020). The abbreviation of model and assimilation framework is**  
235 **explained in Table 1.**

236

237 The experiment consisted of six steps:

238 Step 1: initialize the LPJ-DGVM and output the reference state variables without assimilation over  
239 the experimental period (2010–2018), referred to as the “Control run” scenario.

240 Step 2: implement ~~schemes 1, 2, and 3~~, three assimilation schemes respectively, and the results  
241 represent the assimilation integration state (daily GPP and ET assimilation results are referred to as the  
242 “GPP<sub>LAI</sub>” and “ET<sub>LAI</sub>” in ~~scheme 1~~ LAI-only scheme; “GPP<sub>SM</sub>” and “ET<sub>SM</sub>” in SSM-only scheme ~~scheme~~  
243 ~~2~~ and “GPP<sub>joint</sub> ~~GPP<sub>ee</sub>~~” and “ET<sub>joint</sub> ~~ET<sub>ee</sub>~~” in Joint LAI and SSM assimilation scheme ~~scheme 3~~. This  
244 scenario used the same input data and model parameter scheme with the “Control run” scenario.

245 Step 3: evaluate GPP and ET results (~~three~~ ~~schemes 1, 2 and 3~~) by comparing the parameters, R<sup>2</sup>  
246 (correlation coefficient), BIAS, and ubRMSD (unbiased root mean square deviation), for conditions of  
247 without-DA (“Control run” scenario) and with-DA states, and assess the assimilation performance of  
248 separate assimilation (~~schemes 1 and 2~~) and joint assimilation (~~scheme 3~~) to determine the optimal  
249 assimilation scheme for GPP and ET, respectively.

250 Step 4: evaluate the in-situ GPP and ET resulting from the assimilation ~~assimilated GPP and ET~~  
251 ~~results~~ where the sites are located in wet or dry regions by dividing these validation sites into four parts

252 (humid, sub-dry humid, semi-arid, and arid regions), and this step was designed to assess the superiority  
253 of the proposed assimilation scheme in water-limited areas.

254 Step 5: compare the ET assimilation performance by assimilating the SMOS data with that by  
255 assimilating the SMAP data.

256 Step 6: evaluate the simulated GPP and ET maps based on the optimal assimilation scheme against  
257 existing global flux products.

### 258 2.2.1 LAI-only assimilation scheme~~DA scheme 1: LAI assimilation~~

259 In ~~the LAI-only assimilation scheme~~assimilation scheme 1, the observation operator determines  
260 the relationship between LAI and foliage projective cover (FPC) in the process model (equation 2.1), and  
261 the assimilated LAI will be propagated by energy transmission and ecosystem processes (e.g.  
262 photosynthesis, transpiration of vegetative process) in the dynamic model to improve GPP and ET  
263 simulations (Bonan et al. 2014; Mu et al. 2007). FPC, the vertically projected percentage of the land  
264 covered by foliage, regulates the rate of photosynthate conversion and transpiration. In this study, the  
265 GLASS LAI with 8-day interval for the period 2010–2018 was selected as the observation dataset for  
266 assimilation, and the FPC state variable was updated daily through running the LPJ-PM (FPC<sub>DA</sub>, GPP<sub>LAI</sub>,  
267 ET<sub>LAI</sub> in this study) as shown below:

$$268 \quad FPC = 1 - e^{-0.5LAI} \quad (2.1)$$

269 We set the model and observation errors at a given time as 20% and 10% (scale factor) of the LAI  
270 value and the observed LAI value, respectively. By verifying the assimilation performance ( $R^2$ , RMSD,  
271 BIAS) for different scale factors( $f$ ) of model simulation and observations in the range of 0.05 to 0.40,  
272 taking a step size of 0.05 (a total of 64 combinations), the optimal scale factors (0.2 and 0.1) were  
273 determined (Bonan et al., 2020).The model and observation errors was the LAI value multiplied by  $f$ .  
274 The model integration generation method described by Pipunic et al. (2008) was used to determine the  
275 minimum number of ensemble members required to achieve maximum efficiency, and the number of sets  
276 was 20.

### 277 2.2.2 ~~SSM-only assimilation scheme~~ ~~DA scheme 2: SSM assimilation~~

278 In this scheme, the ~~surface~~-SSM products (SMOS or SMAP) were assimilated into LPJ-PM to  
279 obtain more accurate ET ( $ET_{SM}$ ) estimates in water-limited areas. The observation series was the SMOS  
280 or SMAP SSM product, and the observation operator was the PT-JPL<sub>SM</sub> model. The  $ET_{PM}$  (see Table 1)  
281 was estimated by the coupled model (LPJ-PM) introducing ~~surface~~-SSM ~~was directly assimilated~~ as a  
282 diagnostic variable. The ET values resulting from the assimilation~~assimilated ET~~ was applied to compute  
283 the top layer SM (50 cm) at the next time step (a nonlinear soil water availability function described by  
284 Zhao et al. (2013), providing feedback for subsequent hydrologic and carbon cycle processes. Then, the  
285 updated SM values regulated the GPP simulation (output:  $GPP_{SM}$ ). Different from other "constant" ET  
286 observations, the  $ET_{PM}$  ("observation") at each time  $t$  were adjusted by absorbing intermediate variables  
287 updated after assimilation at time  $t-1$ . The  $ET_{PM}$  was shown to be better than ET simulated by LPJ-DGVM

288 but not as good as that simulated by the model with SMAP SSM assimilated (Li et al. 2020). Thus, it is  
289 also proven that this SSM assimilation schemes could improve the accuracy of ET simulations (Li et al.  
290 2020).

291 All assimilation simulations were conducted between January 2010 and December 2018. Between  
292 January 2010 and April 2015, SMOS data were used for assimilation; and after May 2015, both SMOS  
293 and SMAP data were used for assimilation. An assimilation scheme was conducted when RH and SMOS  
294 or SMAP SSM data existed simultaneously; otherwise, the original simulation of the LPJ-DGVM was  
295 conducted directly without adjustment of assimilation.

296 Similar to the LAI assimilation scheme, the model and observation errors were set as 15% and 5%  
297 of  $ET_{LPJ}$  and  $ET_{PM}$ , respectively (LPJ-PM was adopted before assimilation). The number of ensemble  
298 members was set to 50. The  $ET_{PM}$  must be rescaled to the  $ET_{LPJ}$  distribution via their corresponding  
299 cumulative probabilities using the cumulative distribution function (CDF) matching to avoid introducing  
300 any bias-BIAS in the LPJ-VSJA system (Li et al. 2020).

### 301 2.2.3 Joint LAI and SSM assimilation scheme ~~DA scheme 3: joint assimilation of LAI and SSM~~

302 In this scheme, both LAI from GLASS and SSM from SMOS or SMAP were the observation datasets.  
303 The GLASS LAI was assimilated ~~by scheme 1~~ to obtain the  $FPC_{DA}$  and  $ET_{LAI}$ , and then the  $FPC_{DA}$  served  
304 as input to LPJ-PM to simulate optimized  $ET_{PM}$ , and the  $ET_{joint}$  was generated using  $ET_{LAI}$  and was  
305 ~~further assimilated with  $ET_{PM}$  to generate  $ET_{PMCO}$~~ . Then, the SM (referred to as  $SM_{CO}$  in Figure S1)

306 updated by ~~ET<sub>joint</sub>~~ and the FPC<sub>DA</sub> were used as input to correct GPP  
307 (~~ET<sub>joint</sub>~~).

308 Here, we applied the error regulation in the LAI-only scheme and maintained the error  
309 setting of the LAI observation and model simulation. Considering the transmission of integrated model  
310 error, we recalculated the model error of LPJ-PM after the LAI assimilation and set model and observation  
311 errors of ET<sub>LAI</sub> and ET<sub>PM</sub> to be 15 and 10%, respectively.

### 312 *2.3. POD-Based Ensemble 4D Variational Assimilation Method*

313 The Proper Orthogonal Decomposition (POD)-based ensemble four-dimensional variational (4DVar)  
314 assimilation method (referred to as PODEn4DVar) (Tian and Feng 2015) has the advantage of avoiding  
315 the calculation of adjoint patterns as its incremental analysis field, which can be represented linearly by  
316 the POD base (Transformed OP (Observing Perturbation) and MP (Model Perturbation)). Moreover, the  
317 PODEn4DVar can simultaneously assimilate multiple-time observation data and provide flow-dependent  
318 (the flow-dependent is the ensembles of forecasting statistical characteristics in the t time) error estimates  
319 of the background errors. It has shown advantages in terrestrial assimilation, Tan-Tracker system  
320 DA (a Chinese carbon cycle data-assimilation system; in Chinese, “Tan” means carbon), and Radar  
321 assimilation (Tian et al. 2010; Tian et al. 2009; Tian et al. 2014; Zhang and Weng 2015).

322 By minimizing the following initial incremental format of the cost function in the 4DVar algorithm,  
323 an analysis field can be obtained:

$$J(x') = \frac{1}{2}(x')B^{-1}(x') + \frac{1}{2}[y'(x') - y'_{obs}]^T R^{-1}[y'(x') - y'_{obs}]$$

324

325

326

327

328

329

330

331

332

333

334

Here, the  $x' = x - x_b$ ,  $y'(x') = y(x' + x_b) - y(x_b)$ ,  $y'_{obs} = y_{obs} - y(x_b)$ ,  $y = H[M_{t_o \rightarrow t_k}(x)]$ .

$x'(x'_1, x'_2, \dots, x'_N)$  is the model perturbation (MP) matrix and  $y'(y'_1, y'_2, \dots, y'_N)$  is the observation perturbation (OP) matrix with N samples. Following Rüdiger et al. (2010), the LAI perturbation was set to a fraction (0.001) of the LAI itself. The perturbation of  $ET_{PM}$  and  $ET_{LPJ}$  conforms to a Gaussian distribution with a mean of 0 and a specified covariance (10 and 5% of the  $ET_{PM}$  and  $ET_{LPJ}$  at time t). The subscript b represents the background field, the superscript T represents a transpose, H is the observation operator of [the scheme 1 LAI-only assimilation scheme](#) as described in section 2.2.1, and [the scheme 2 SSM-only assimilation scheme](#) is the PT-JPL<sub>SM</sub> (described in 2.1.2). M is the forecast model (LPJ-PM in this study), B is the background error covariance, R is the observation error covariance, and obs denotes observation.

335

336

337

338

Assuming the approximately linear relationship between OP( $y'$ ) and MP( $x'$ ), POD decomposition and transformation were successively conducted for OP and MP. The transformed OP samples ( $\Phi_y = y'_1, y'_2, \dots, y'_n$ ) are orthogonal and independent, and the transformed MP samples ( $\Phi_x = x'_1, x'_2, \dots, x'_n$ ) are orthogonal to the corresponding OP samples, where n is the number of POD modes.

339

340

341

The manifestation of the background error covariance is the same as the Ensemble Kalman filter (EnKF, Evensen (2004)), and the incremental analysis  $x'_a$  was expressed by the  $\Phi_{x,n}$ , and  $\tilde{\Phi}_y(\tilde{\Phi}_y = [(n-1)I_{n \times n} + \Phi_{y,n}^T R^{-1} \Phi_{y,n}]^{-1} \Phi_{y,n}^T R^{-1})$ . Finally, the optimal analysis  $x_a$  is calculated as  $x_a = x_b +$

342  $\Phi_{x,n} \tilde{\Phi}_y y'_{obs}$ . The detailed derivation process of the algorithm is described by a previous study (Tian et  
 343 al. 2011).

344 In the ensemble-based method (Evensen et al.,2004), the number of ensemble members is usually  
 345 fewer than that of the observation data and the degrees of freedom of the model variables, and spurious  
 346 long-range correlations occur between observation locations and model variables. A practical method, the  
 347 localization technique, is applied to address this issue (Mitchell et al. 2002). The final incremental analysis  
 348 is rewritten as:

$$349 \quad x'_a = \Phi_{x,n} \tilde{\Phi}_y y'_{obs} C_0\left(\frac{d_h}{d_{h,0}}\right) \cdot C_0\left(\frac{d_v}{d_{v,0}}\right)$$

350 where  $d_h$  and  $d_v$  are the horizontal and vertical distances between the spatial positions of state and  
 351 observed variables, respectively; and  $d_{h,0}$  and  $d_{v,0}$  are the horizontal and vertical covariance localization  
 352 Schur radii, respectively. The filtering function  $C_0$  is expressed as:

$$353 \quad C_0(r) = \begin{cases} -\frac{1}{4}r^5 + \frac{1}{2}r^4 + \frac{5}{8}r^3 - \frac{5}{3}r^2 + 1, & 0 \leq r \leq 1, \\ \frac{1}{12}r^5 - \frac{1}{2}r^4 + \frac{5}{8}r^3 + \frac{5}{3}r^2 - 5r + 4 - \frac{2}{3}r^{-1}, & 1 \leq r \leq 2, \\ 0, & 2 < r \end{cases}$$

354 where  $r$  is the radius of the filter.

355 The assimilation algorithm is mainly divided into two steps: (1) prediction: run LPJ-PM in the  
 356 current assimilation window and generate simulation results and background field vectors; (2) update: the  
 357 algorithm is used to calculate the optimal assimilation increment  $x'_a$  and analysis solution  $x_a$ , and the

358 simulation results and the initial conditions of the model in the current window are updated using the  
359 analysis solution. The updated initial conditions were applied for model LPJ-PM prediction, and the above  
360 process was repeated.

#### 361 *2.4. Validation method for assimilation performance*

362 The  $R^2$  (~~correlation coefficient squared~~ coefficient of determination),  
363 ~~Bias~~BIAS, and ubRMSD (unbiased root mean square deviation) between simulation and tower-based  
364 observations were applied for evaluation. In addition, a Taylor chart was also used to demonstrate the  
365 performance of two ET estimations with different SSM observations in terms of R, ubRMSD, and  
366 Normalized Standard Deviation (NSD) on 2D plots, to display how closely the datasets matched  
367 observations in one diagram (Taylor 2001). In the Taylor diagram, NSD represents the radial distance  
368 from the origin point and the correlation with the site observations as an angle in the polar plot. The  
369 ubRMSD is the distance between the observation and the model and is represented in the ~~figure~~Taylor  
370 chart as a green semi-circular arc with point A as the center of the circle. The closer the model point to  
371 the reference point (Point A), the better the performance. This diagram is convenient and visual in  
372 evaluating multiple aspects of various models.

373 The error variance of GPP and ET products was estimated using the triple collocation (TC) approach  
374 (Stoffelen 1998) to validate the global simulation in this study. The method has been extensively applied  
375 in the study of hydrology and oceanography (Caires and Sterl 2003; Khan et al. 2018; O'Carroll et al.  
376 2008; Stoffelen 1998), particularly in SM studies (Chan et al. 2016; Kim et al. 2018). The TC provides a

377 reliable platform for comparison of spatial assimilation results and in-situ measurements. In this  
378 experiment, no calculation was performed on the non-vegetated areas where the correlation was lower  
379 than 0.2 to have independent datasets and avoid correlated errors (crucial assumptions in TC) (Yilmaz  
380 and Crow 2014).

381 In this study, the five products were divided into three product categories, including satellite product  
382 (MODIS, GOSIF GPP), reanalysis product (GLASS, GLDAS) and data assimilation product (GLEAM  
383 ET, LPJ-VSJA) (Li et al.,2018). One product in each category was selected to form a group to calculate  
384 their error. The LPJ-VSJA product was set as the reference data.

385 For GPP products, GOSIF, GLASS, and LPJ-VSJA were treated as a group, and MODIS, GLASS  
386 and LPJ-VSJA were treated as another group to calculate the errors; the final errors were determined by  
387 the average of these two.

388 Similarly, to calculate the errors for ET, GLEAM, GLASS, and MODIS were chosen as a group;  
389 LPJ-VSJA, GLDAS, and MODIS were treated as a group; LPJ-VSJA, GLASS and MODIS were  
390 considered as a group. In order to reduce the influence of orthogonality hypothesis of error, the first and  
391 third groups are for indirect and effective comparison between LPJ-VSJA product and GLEAM product.

### 392 **3. Experiment sites and data**

#### 393 *3.1. Description of flux tower sites*

394 We screened over 300 EC flux sites across the globe from the FLUXNET2015  
395 (<https://fluxnet.fluxdata.org/data/fluxnet2015-dataset/>), AmeriFlux (<http://public.ornl.gov/ameriflux>),

396 and the HeiHe river basin (Liu et al. (2018), <http://www.heihedata.org>) for the evaluation of assimilation  
397 performance over the period from January 2010 to December 2018. The in-situ half-hourly LE and GPP  
398 data from the sites were aggregated into daily data. The daily gap-filled data were excluded if the  
399 percentage of gap-filled half-hourly values was more than 20%. Then we corrected the data of energy  
400 non-closure by using the Bowen ratio closure method (Twine et al. 2000) to improve the energy closure  
401 rate (Huang et al. 2015; Yang et al. 2020). The data were selected to cover the 2010–2018 period with at  
402 least one year of reliable data, and the result from the error of assimilation is relative to the LE value and  
403 seasonal variation (Purdy et al. 2018; Zou et al. 2017). It is essential to have available data every month  
404 during a one-year period, and only days with less than 25% missing data were processed per month (Feng  
405 et al. 2015). In addition, for flux tower data, the data were also excluded for the analysis if the  
406 SMAP/SMOS SSM data were not of good quality.

407 Finally, we identified a total of 105 sites across the globe encompassing five major biomes: grassland  
408 (18 for GPP and 19 for ET), savanna (11), shrubland (4), forest (49 and 53), and cropland (13 and 14). In  
409 the comparative analysis of the performance for simulating ET by assimilating SMOS and SMAP SSM  
410 data separately, we selected 46 AmeriFlux sites (Figure S3) with at least one year of reliable data from  
411 2015 to 2018 based on the simultaneous availability of SMAP and SMOS data, including grassland (19),  
412 savanna (11), shrubland (5), forest (23), and cropland (7). Figure S2 and S3 illustrate the location and  
413 distribution of the 105 and 46 EC flux tower sites, respectively. A more detailed description is  
414 summarized in the Supporting Information Table S1.

415 3.2. Remote sensing datasets: LAI and SSM

416 The GLASS LAI product with an 8-day time step (8-day average) and 5 km resolution was derived  
417 from MODIS and CYCLOPES surface reflectance and ground observations using general regression  
418 neural networks (GRNNs) (~~Liang et al. 2013; Xiao et al. 2016~~Xiao et al. 2013; Xiao et al. 2016). The  
419 verification of the product using the mean values of high-resolution LAI maps showed that the GLASS  
420 LAI values were closer to these high-resolution LAI maps (RMSD= 0.78 and  $R^2= 0.81$ ) (~~Xiao et al. 2016;~~  
421 Liang et al. 2013). Therefore, the GLASS LAI product has satisfactory performance and can be  
422 assimilated into terrestrial biosphere models.

423 The SMAP mission (Entekhabi et al. 2010) and SMOS mission (Jacquette et al. 2010), the two  
424 dedicated soil moisture satellites currently in orbit equipped with L-band microwave instruments, provide  
425 ~~surface-~~SSM retrievals. We chose the SMOS-L2 product and the SMAP-L3-Enhanced product, which  
426 both provide global coverage every three days for soil depth of 5 cm. Only good-quality SMAP and  
427 SMOS data were used. The grid cells with water areas larger than 10% and those with less than 50%  
428 good-quality data in one year were masked out, which alleviates the undesirable model simulations caused  
429 by the decrease in SMAP retrieval accuracy (Chan et al. 2016; O'Neill et al. 2010). We only adopted the  
430 data with an uncertainty below  $0.1 \text{ m}^3 \text{ m}^{-3}$ , in the actual range ( $0.00\text{--}0.6 \text{ m}^3 \text{ m}^{-3}$ ), and the temperature of  
431 the LSM observation layer (the second layer) was higher than  $2 \text{ }^\circ\text{C}$  (Blyverket et al. 2019).

432 ~~Both~~ The GLASS LAI, SMOS and SMAP observations ~~was~~ were resampled to 9 km for site  
433 simulation and 0.25° for ~~spatial~~ regional simulation. The 8- day average of GLASS LAI were assimilated  
434 for each day, and the SMAP or SMOS SSM was assimilated every 3 days.

### 435 3.3. Model-forcing and validation datasets

436 In this study, the meteorological, soil property, and CO<sub>2</sub> concentration datasets were used to drive  
437 the LPJ-PM. The climate-driven ~~dataset~~ datasets used for the initialization of the LPJ-DGVM are the  
438 Atmospheric CO<sub>2</sub> concentrations (1901-2018) of ice-core measurements and atmospheric  
439 observations at the Mauna Loa Observatory and CRU TS4.03 version Climate data from 1901 to 1930  
440 provided by the Climatic Research Unit (CRU) of the Climate Laboratory, University of East Anglia, UK,  
441 including monthly precipitation, surface temperature, cloud cover and wet day. In the simulation period  
442 of 2010-2018, the Modern Era Retrospective-Analysis for Research and Applications Version 2  
443 (MERRA-2) was ~~used~~ adopted, and the variables used including precipitation, temperature, cloud cover  
444 and relative humidity. Soil properties (including limited water content of vegetation at wilting points,  
445 field capacity and Soil porosity) from Harmonized World Soil Database (HWSD) V1.2 dataset (Wieder  
446 et al. 2014) were selected as inputs to the PT-JPLSM model. Table 2 provides the spatial and temporal  
447 characteristics of the model-forcing datasets in the LPJ-PM (submodule: LPJ-DGVM and PT-JPL<sub>SM</sub>).

448 The GLASS LAI product, SMOS-L2 product and the SMAP-L3-Enhanced product were assimilated  
449 to ~~produce~~ simulate GPP and ET. For site simulation, in order to maintain consistency with the SMAP  
450 Enhanced 3 Level product (Entekhabi et al. 2010), model-forcing data were resampled to a 9 km spatial

451 resolution based on EASE-2 projection grid. In the global spatial simulation, the model-forcing datasets  
 452 ~~were resampled~~~~were interpolated~~ to 0.25° based on the bilinear method to ensure the consistency of spatial  
 453 representation. ~~Table 2 provides the spatial and temporal characteristics of the model forcing datasets in~~  
 454 ~~the LPJ-PM (submodule: LPJ-DGVM and PT-JPL<sub>SM</sub>).~~

455

464

465 **4. Results**

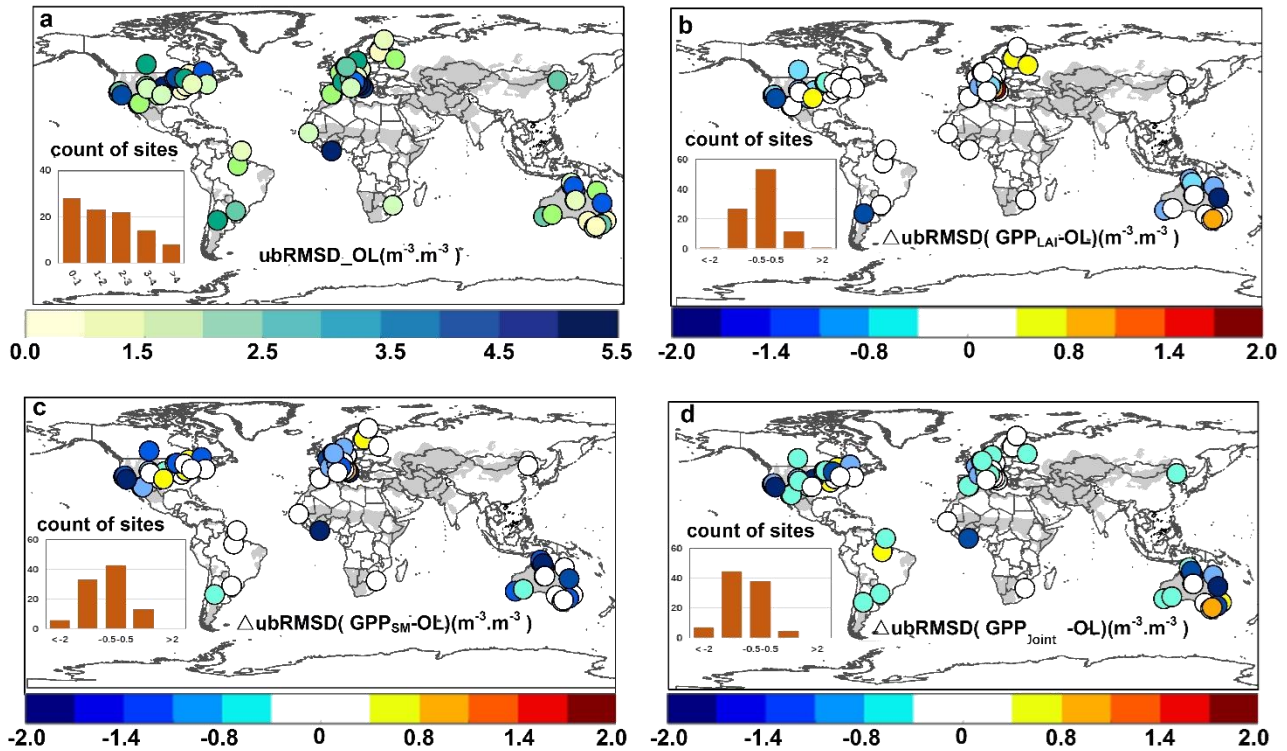

466 4.1. Performance of LPJ-PM for simulating GPP and ET with the assimilation of LAI and soil moisture

467 4.1.1 Accuracy assessment of GPP for separate and joint assimilation

468 In general, the  $R^2$  between  $GPP_{LPJ}$  and  $GPP_{OBS}$  was above 0.4 at most of the sites (62 sites) and  
469 were relatively weak for some sites. The LAI assimilation improved the simulations at most sites ( $R^2$   
470 value increased at 82 sites), particularly for sites in the U.S. and Europe (Figure S2S4). The  $R^2$   
471 improvement from the LAI assimilation (~~scheme 1~~ LAI-only assimilation) was superior to that from the  
472 SSM assimilation (Figure S42-R<sup>2</sup> (b) and (c)). The performance of the joint assimilation (~~scheme 3~~) was  
473 similar to that of ~~scheme 1~~ LAI-only assimilation. Sites (Figure S52-BIAS (a)) showed positive  
474 BIAS ( $GPP_{OBS} - GPP_{LPJ}$ ) were mainly distributed in the humid and ~~sub-dry~~ dry-sub humid forest,  
475 grassland, and arid cropland regions, showing an underestimation for  $GPP_{OBS}$ . The assimilation  
476 improved the accuracy for overestimated sites, but there was no significant improvement for  
477 underestimated sites. The ubRMSD implied that the SSM assimilation alone had a better performance  
478 than the LAI assimilation alone, especially for sites in arid areas (Figure 2). The analysis of the above  
479 three statistical measures ( $R^2$ , BIAS, and ubRMSD) indicated that the accuracy of joint assimilation was  
480 much better than that of separate assimilation.

481 At the seasonal scale, all three assimilation schemes corrected the model trajectory and  
482 significantly improved the growing season simulations, especially for peak values (IT-Tor, US-NR1,  
483 US-NE1) (Figure 3). In addition, the linear fitting of  $GPP_{joint}$   ~~$GPP_{co}$~~   $GPP_{JOINT}$  and  $GPP_{OBS}$  on a  
484 monthly scale was closer to 1:1 ( $y = 0.92x + 21.66$ ,  $p < 0.001$ ) than that of  $GPP_{LAI}$  ( $y = 0.89x + 28.3$ ,  $p <$

485 0.001) and  $GPP_{SM}$  ( $y = 0.86x + 41.70$ ,  $p < 0.001$ ) (Figure S5S9). The results in Table S2 support the  
 486 above analysis, and the joint assimilation showed advantages in overall accuracy in both arid and humid  
 487 areas.

488

Figure 2 (a)The Unbiased Root Mean Square Error ( $ubRMSE_{ubRMSD}$ ) between the  $GPP(GPP_{LPJ})$  simulated by the LPJ-DGVM and the site observations, the yellow/blue indicating low/high correlation  $ubRMSD$ ; (b)  $\Delta ubRMSD(GPP_{LAI} - GPP_{LPJ})$ ; (c)  $\Delta ubRMSD(GPP_{SM} - GPP_{LPJ})$ ; (d)  $\Delta ubRMSD(GPP_{Joint} - GPP_{LPJ})$ , blue/red represent positive/negative values.

492

**Figure 3. Seasonal cycles of tower GPP and simulated gross primary productivity (GPP) from Lund-Potsdam-Jena (LPJ), GLASS LAI assimilation (scheme 1) LAI-only assimilation, SMOS assimilation (scheme 2) SSM-only assimilation and joint assimilation (scheme 3) for six sites representing six PFTs.**

493 The residual analysis indicated that the three assimilation schemes for GPP (Figure S11-S11 (left))  
 494 were different. For the assimilation results, most of the errors were distributed around  $-70 \sim 60 \text{ g C m}^{-2}$   
 495  $\text{month}^{-1}$ . The high  $\text{GPP}_{\text{OBS}}$  values were considerably underestimated. The maximum negative error  
 496 reached  $100 \text{ g C m}^{-2} \text{ month}^{-1}$ . The error distribution of  $\text{GPP}_{\text{SM}}$  was more dispersed than that of  $\text{GPP}_{\text{LAI}}$   
 497 and  $\text{GPP}_{\text{ce}}/\text{GPP}_{\text{joint}}$ . Among the residuals of these three schemes,  $\text{GPP}_{\text{SM}}$  significantly overestimated the  
 498  $\text{GPP}_{\text{OBS}}$ , mainly distributed in the  $0\text{--}200 \text{ g C m}^{-2} \text{ month}^{-1}$  range.  $\text{GPP}_{\text{LAI}}$  showed significant improvement  
 499 in the overestimation of  $\text{GPP}_{\text{OBS}}$  compared with  $\text{GPP}_{\text{ce}}/\text{GPP}_{\text{joint}}$ . In general, the  $\text{GPP}_{\text{joint}}/\text{GPP}_{\text{ce}}$  with the  
 500 most concentrated error distribution had significant improvement.

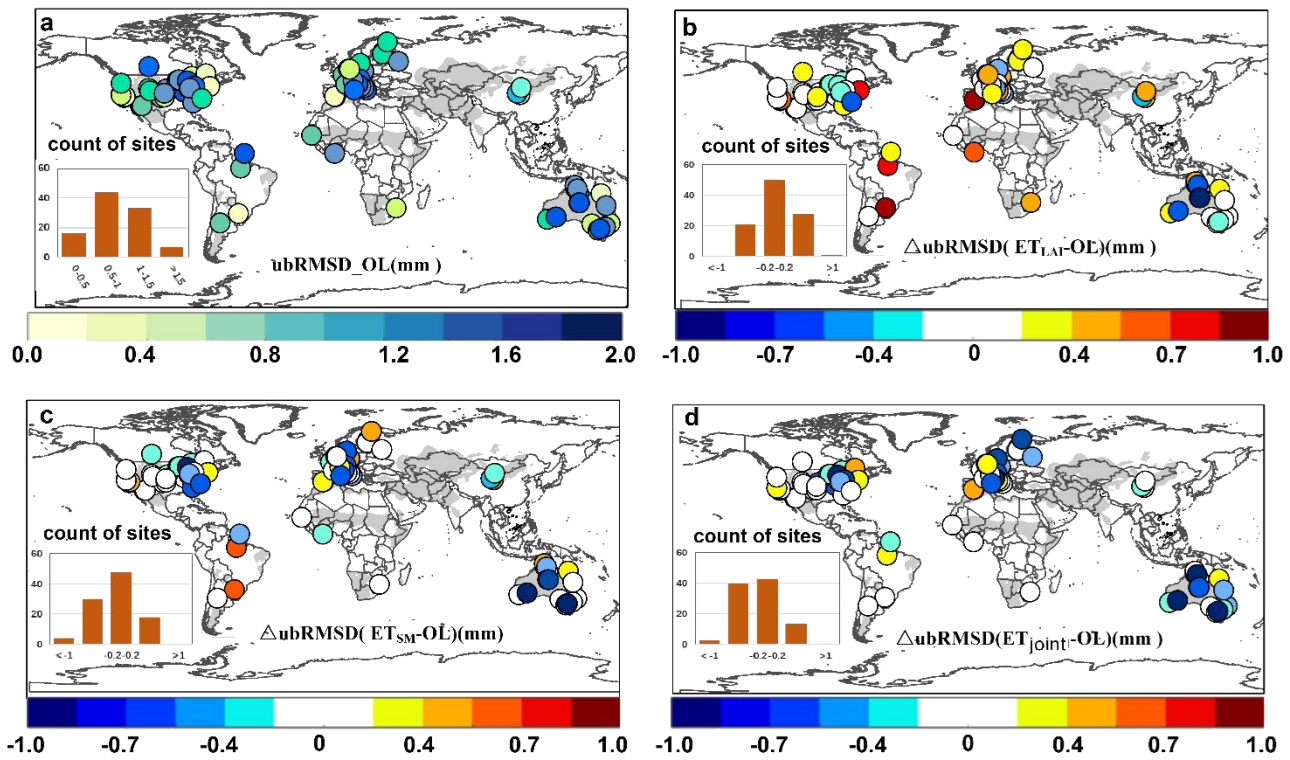

501  
 502 **Figure 4. Scatterplots of daily  $\text{GPP}_{\text{LPJ}}$  (left) and  $\text{GPP}_{\text{joint}}/\text{GPP}_{\text{ce}}$  (right) versus tower GPP for different**  
 503 **PFTs.**

504 After determining the optimal assimilation scheme (~~scheme 3~~ Joint LAI and SSM assimilation  
505 scheme), we evaluated the  $GPP_{LPJ}$  and  $GPP_{joint}$  ~~$GPP_{co}$~~  at the site level (Figure.4). The results showed that  
506  $GPP_{joint}$  ~~$GPP_{co}$~~  performed better ( $R^2= 0.83$ , ubRMSD=  $1.15 \text{ g C m}^{-2} \text{ d}^{-1}$ ) than  $GPP_{LPJ}$  ( $R^2= 0.69$ ,  
507 ubRMSD=  $1.91 \text{ g C m}^{-2} \text{ d}^{-1}$ ). The noticeable underestimation in all PFTs and overestimation at most forest  
508 sites for  $GPP_{LPJ}$  were corrected by joint assimilation ( $GPP_{joint}$  ~~$GPP_{co}$~~ ). Our joint assimilation methods  
509 had better performance in forests, shrublands, and grasslands than in croplands and savannas. Except for  
510 the cropland, the linear fitting results of other types were all below the 1:1 line, showing the overall  
511 underestimation. Superior performance in both original simulation and assimilation occurred at shrubland  
512 ( $R^2= 0.93$ , ubRMSD=  $0.89 \text{ g C m}^{-2} \text{ d}^{-1}$ ) and grassland ( $R^2= 0.97$ , ubRMSD=  $0.83 \text{ g C m}^{-2} \text{ d}^{-1}$ ) sites.  
513 However, the standard deviation of  $GPP_{joint}$  ~~$GPP_{co}$~~  and  $GPP_{OBS}$  at savanna sites was relatively large, and  
514 the ~~assimilated  $GPP$~~  $GPP_{joint}$  ~~$GPP_{co}$~~  at several savanna sites was significantly underestimated.

#### 515 4.1.2 Accuracy assessment of ET for separate and joint assimilation

516 In general, the coefficient of determination ( $R^2$ ) between  $ET_{LPJ}$  and  $ET_{OBS}$  was generally over 0.4  
517 (the simulations were superior to  $GPP_{LPJ}$ ) (Figure 5S6).  $ET_{LAI}$  showed slightly higher  $R^2$ , while some  
518 sites showed reduced values (41 sites). The  $ET_{SM}$  and  ~~$ET_{co}$~~  $ET_{joint}$  were significantly improved  
519 compared with the  $ET_{LAI}$ . The  $R^2$  increased considerably in Australia but declined at some sites in the  
520 United States after assimilation. For ubRMSD,  $ET_{joint}$  ~~$ET_{co}$~~  performed better than  $ET_{SM}$  and

521 ET<sub>LAI</sub>. The SSM assimilation improved more in humid regions, while the ubRMSD of ET<sub>SM</sub> was  
 522 slightly higher in South America (Figure 5). In the original LPJ-DGVM simulation, the sites with a  
 523 negative BIAS bias were mostly located in the humid and dry-subsub-dry humid regions, while most of  
 524 the sites in arid and semi-arid regions had underestimation (Figure. 5S7- BIAS(a), Table S3). The  
 525 assimilation improved ET at some of the overestimated sites, but the underestimation over these sites  
 526 showed little improvement.

527

**Figure 5 (a) The Unbiased Root Mean Square Error (ubRMSE) between the ET simulated by the LPJ-DGVM and the site observations, with yellow/blue indicating low/high ΔubRMSD; (b) ΔubRMSD (ET<sub>LAI</sub>-ET<sub>LPJ</sub>); (c) ΔubRMSD (ET<sub>SM</sub>-ET<sub>LPJ</sub>); (d) ΔubRMSD (ET<sub>Joint</sub>-ET<sub>LPJ</sub>), blue/red represent positive/negative value.**

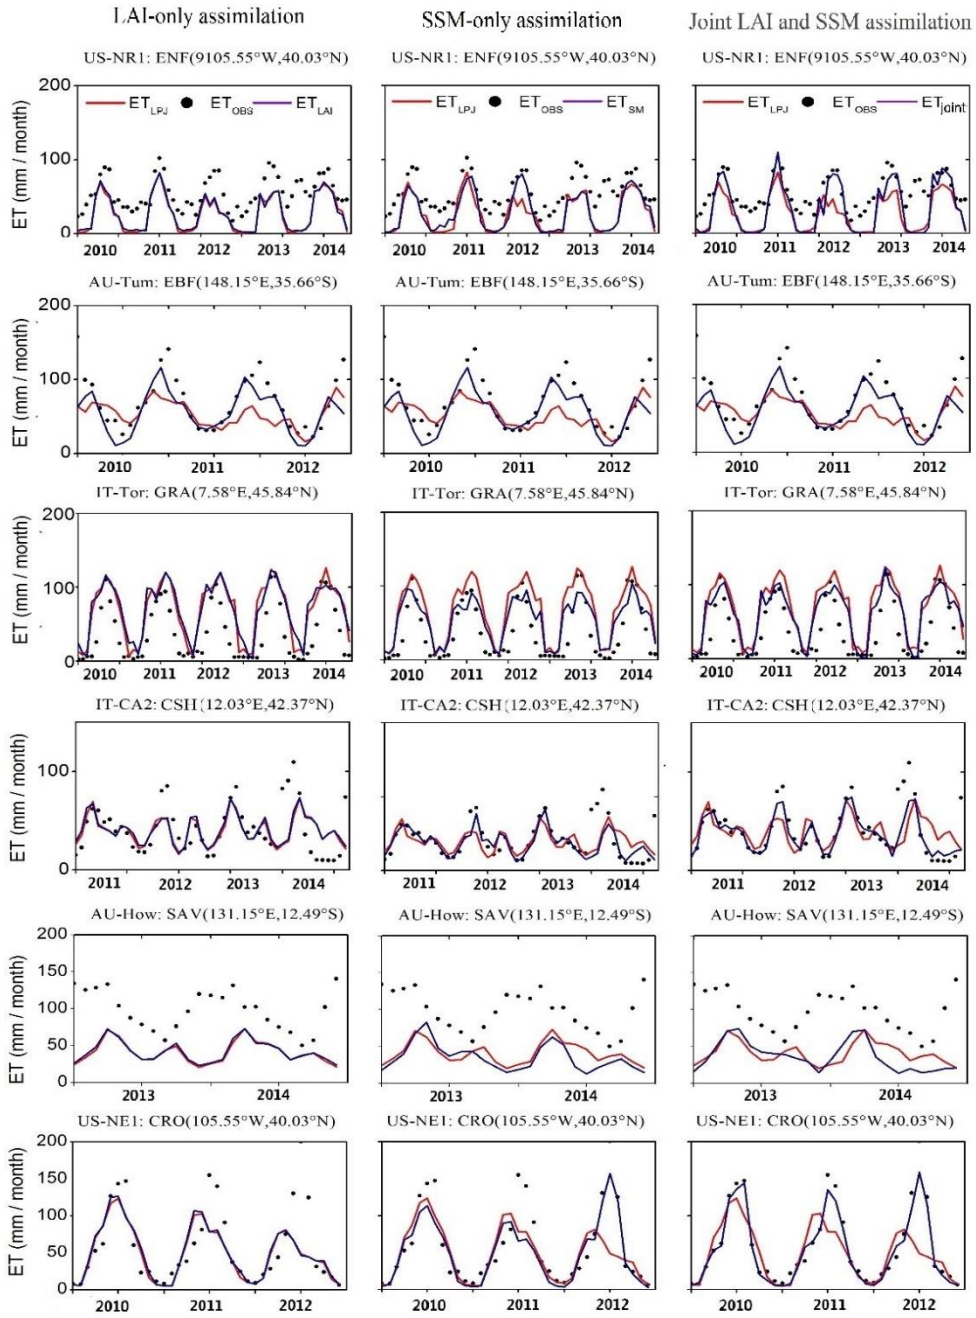

529 At the seasonal scale, the model simulations were able to capture the temporal trend of  $ET_{OBS}$ , and  
530 joint assimilation significantly improved the simulation in the growing season (US-NR1, US-NE1);  
531 overall underestimation was observed for  $ET_{OBS}$ , especially in winter (Figure 6). Overall, the linear fitting  
532 of monthly  $ET_{joint}$  and  $ET_{OBS}$  was closer to 1:1 than that of  $ET_{LAI}$  and  $ET_{SM}$  (Figure S10). The  
533 simulation accuracy of joint assimilation was better than that of separate assimilation, and the  
534 performance of the  $SSM$  assimilation was better than that of the LAI assimilation.

535 The ET residual analysis (Figure S7-S11 (right)) indicated that the three assimilation scheme errors  
536 showed underestimation for  $ET_{OBS}$ . In general, the error distribution of separate assimilations was more  
537 dispersed than that of the joint assimilation. Similar to the assimilation performance of GPP,  $ET_{joint}$   
538 and  $ET_{SM}$  significantly improved the overestimation of  $ET_{OBS}$ , but did not significantly improve the  
539 underestimation. For the  $ET_{joint}$ , most of the errors were distributed around -30–18 mm month<sup>-1</sup>.  
540 The region with high  $ET_{OBS}$  was considerably underestimated, and the maximum negative error reached  
541 -57 mm month<sup>-1</sup>.

542 We also evaluated the ET assimilation results at the PFT scale (Figure 7). The results showed that  
543 our ET values resulting from the assimilation performed better at the site level ( $R^2= 0.77$ ,  
544  $ubRMSD= 0.65$  mm d<sup>-1</sup>) than that of  $ET_{LPJ}$  ( $R^2= 0.67$ ,  $ubRMSD=0.95$  mm d<sup>-1</sup>). Joint assimilation  
545 significantly reduced the errors of those shrubland sites with overestimation for  $ET_{OBS}$ , and the site  
546 distribution was closer to the 1:1 line. Our assimilation methods had better performance in forest, savanna,  
547 and grassland ecosystems than in cropland and shrubland (Table S3). The linear fitting results of grassland  
548 and shrubland were all above the 1:1 line, showing overall overestimation. Although the original

549 simulation and assimilation performance were superior at savanna sites ( $R^2= 0.95$ , ubRMSD= 0.78 mm  
550  $d^{-1}$ ), the standard deviations of  $ET_{joint}$  and  $ET_{ce}$  and  $ET_{OBS}$  at savanna sites were relatively large, which was  
551 similar to the GPP results at savanna sites.

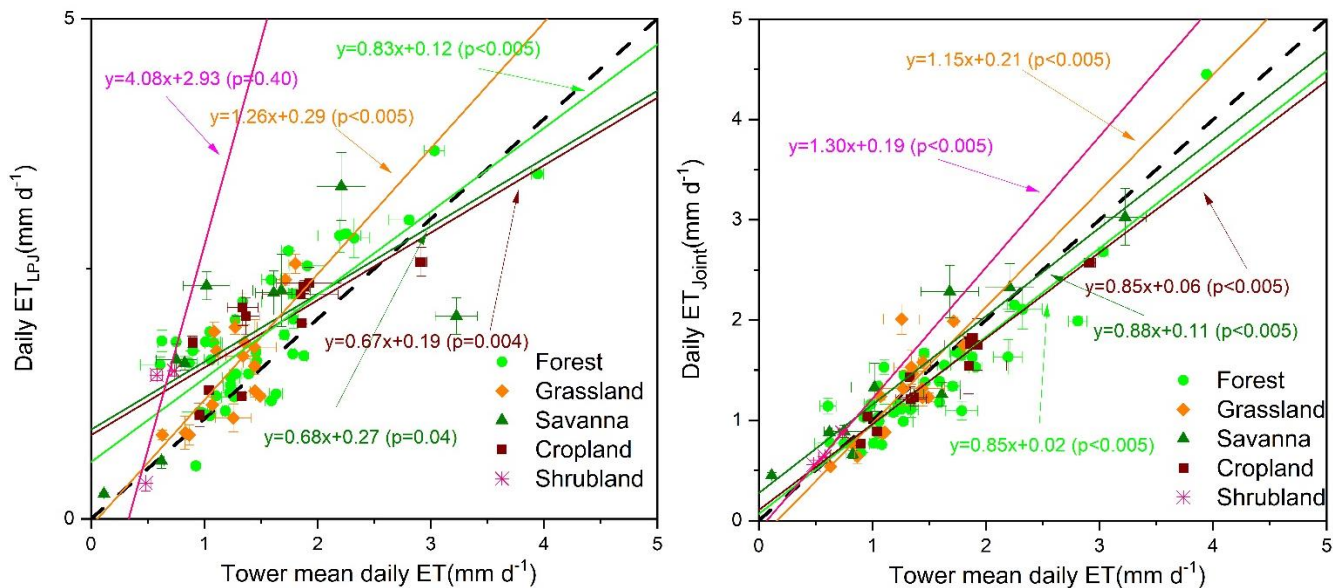

552

553 **Figure 6. Seasonal cycles of tower-based and simulated ET from Lund-Potsdam-Jena (LPJ), [GLASS LAI](#)**

554 ~~assimilation (scheme 1)~~ LAI-only assimilation, SSM-only assimilation ~~SMOS assimilation (scheme 2)~~ and  
 555 joint assimilation (scheme 3) for the six sites representing six PFTs during the study period.

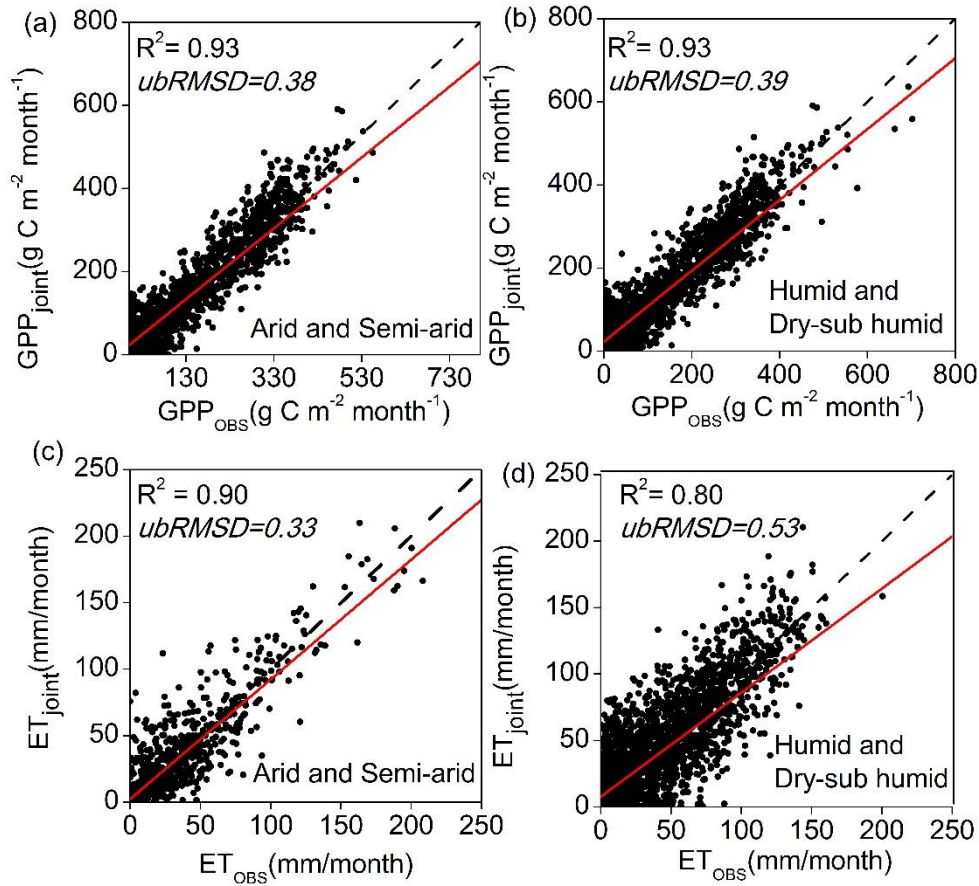

556

557

Figure 7. Scatter plots of daily  $ET_{joint}$  versus tower ET under different PFTs.

558 4.2. Comparison of assimilation performance in semi-arid and arid regions with that in humid and ~~dry~~  
 559 ~~sub~~ sub-dry humid regions

560

561 **Figure 8.** Scatter plots of daily tower GPP and ET versus  $GPP_{joint}$  $GPP_{co}$  and  $ET_{joint}$  $ET_{co}$  under arid and  
 562 **humid sites: (a) and (c) are the fitting results of GPP and ET in arid and semi-arid regions, respectively;**  
 563 **(b) and (d) are the fitting results of GPP and ET in humid and dry sub-humid zone, respectively.**

564

565

566

During the period 2010–2014, monthly  $GPP_{joint}$  $GPP_{co}$  and  $ET_{joint}$  $ET_{co}$  performed differently in humid and sub-dry humid regions and semi-arid and arid regions (Figure 8, Table S2,3). Overall, the GPP and ET simulations had good consistency with the tower data in the two regions. For

567 GPP<sub>joint</sub>~~GPP<sub>joint</sub>~~GPP<sub>co</sub>, there was no significant difference in the correlation and fitting coefficients  
568 between the two regions. As for ET<sub>joint</sub>~~ET<sub>co</sub>~~, the fitting results and R<sup>2</sup> values in the semi-arid and arid  
569 regions performed better than those in the humid and sub-dry humid regions, which also suggested the  
570 importance of ~~surface~~SSM for ET estimation in water-limited areas.

571 On the daily scale, the original GPP simulations (GPP<sub>LPJ</sub>) performed better in the semi-arid and  
572 arid regions than in the humid and sub-dry humid regions with higher R<sup>2</sup> and lower ubRMSD (Table S2).  
573 the R<sup>2</sup> and BIAS~~bias~~ implied that the LAI assimilation alone had a better performance than the SSM  
574 assimilation alone. However, for sites in arid and semi-arid areas, the ~~RMSD~~~~and~~ubRMSD showed that  
575 the GPP<sub>SM</sub> improved better than GPP<sub>LAI</sub>, which both demonstrated SSM data are essential in water-limited  
576 regions. For GPP<sub>joint</sub>~~GPP<sub>co</sub>~~, the shrubland in the semi-arid and arid regions had the lowest R<sup>2</sup> values and  
577 the second lowest ubRMSD. The forest in the semi-arid and arid regions had the largest improvement  
578 after assimilation. In the humid and sub-dry humid regions, the GPP<sub>joint</sub>~~GPP<sub>co</sub>~~ of the savanna and  
579 cropland showed the largest improvement (R<sup>2</sup> increased by 64.7% and 71.1%, respectively; ubRMSD  
580 decreased by 47.0% and 31.8%, respectively). The grassland in the semi-arid and arid regions had the  
581 highest R<sup>2</sup>, and the savanna by combining all indicators had the best assimilation results compared to  
582 other types in both regions.

583 Similar to ET<sub>joint</sub>~~ET<sub>co</sub>~~, the ET<sub>LPJ</sub> in the semi-arid and arid regions was better than that in humid and  
584 sub-dry humid regions in terms of four evaluation indicators (ubRMSD decreased by 34.4% in semi-arid  
585 and arid regions and the ubRMSD decreased by 30.9% in humid and sub-dry humid regions compared

586 with  $ET_{LPJ}$ ). The  $R^2$  and ubRMSD implied that the SSM assimilation alone had a better performance than  
 587 the LAI assimilation alone, especially for sites in arid areas. and the BIAS bias showed that the  $ET_{LAI}$   
 588 improved better than  $ET_{SM}$  for sites in humid and sub-dry humid areas. The performance of the original  
 589 simulation and assimilation of grassland sites in the semi-arid and arid regions was the best among all  
 590 five PFTs.

591

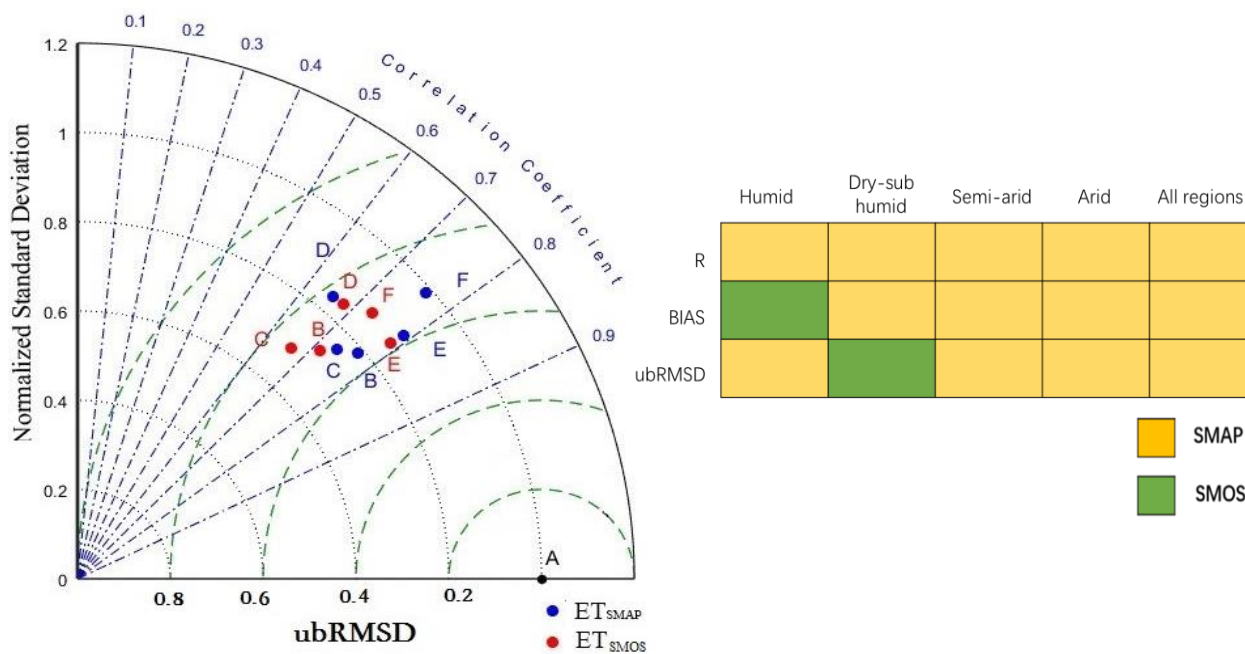

592

593 **Figure 9. Boxplots of  $R^2$ , ubRMSD and BIAS for  $GPP_{SM}$  (left) and  $ET_{PM}$  (right). A represents the sites in arid**  
 594 **and semi-arid areas, and B represents the sites in humid and dry sub-humid areas.**

595 To investigate the reasons for better assimilation performance in water-limited regions, we evaluated  
 596 the GPP and ET simulated by the LPJ-PM according to  $R^2$ , ubRMSD, and BIAS (Figure 79). Compared  
 597 with the semi-arid and arid regions, the humid and sub-dry humid region had smaller  $R^2$  mean, larger

598 BIAS, and no significant difference in mean ubRMSD for GPP<sub>SM</sub>. In general, the evaluation results of  
 599 joint assimilation for ET<sub>PM</sub> were generally consistent with those for GPP<sub>SM</sub> and GPP<sub>SM</sub>. ET<sub>PM</sub> showed  
 600 underestimation, which was consistent with the underestimation in SSM assimilation. These results  
 601 indicated that, both GPP and ET modeled by LPJ-PM with joint assimilation were less stable and had a  
 602 lower performance in the humid and sub-dry regions than in the semi-arid and arid regions.

603 *4.3. Comparison of assimilation performance in assimilating SMOS and SMAP soil moisture data*

A: Reference point B: Cropland C: Shurbland D: Forest E: Grassland F: Savanna

604  
 605 **Figure 10. Taylor diagram (left) comparing ET simulations with observations at all 46 AmeriFlux sites**  
 606 **at the daily time step between April 2015 and December 2018. Blue dots represent results based on**  
 607 **assimilation with SMAP SSM only and red dots represent results based on assimilation with SMOS SSM**  
 608 **only. ubRMSD refers to the dashed green lines. Reference points A and B-F correspond to the vegetation**

609 **functional types (PFTs). The grid diagram (right) compares the evaluation indices of ET simulations with**  
610 **those of the observed values at all 46 AmeriFlux sites with different wet and dry zones at the daily time step;**  
611 **the yellow cells indicate that ET<sub>SMAP</sub> performs better in the metric, and green cells indicate that ET<sub>SMOS</sub>**  
612 **performs better in the metric.**

613 The Taylor chart was used to compare the assimilation performance of ET<sub>SMAP</sub> and ET<sub>SMOS</sub> at 46  
614 AmeriFlux sites (Figure 10-left). The results showed that ET<sub>SMAP</sub> performed better than ET<sub>SMOS</sub> for ~~all~~  
615 ~~most~~ PFTs, ~~except forest~~. Both ET<sub>SMAP</sub> and ET<sub>SMOS</sub> performed well for grassland (closer to point A), and  
616 there was little difference between R<sup>2</sup> and ~~standardized-ub~~RMSD. The NSD of ET<sub>SMAP</sub> in grassland was  
617 0.88, which was closer to 1 than that of ET<sub>SMOS</sub>. The assimilation of ET in the forest had a lower R<sup>2</sup> and  
618 higher ~~standardized-ub~~RMSD (0.7-0.8) than those of other PFTs, and the NSD of cropland and shrubland  
619 was lower than that of other PFTs (0.6-0.8), indicating that the assimilation for cropland and shrubland  
620 could not reproduce the variations in ET effectively. However, ET<sub>SMAP</sub> showed significant improvement  
621 in R<sup>2</sup> compared with ET<sub>SMOS</sub> for shrubland and cropland. The assimilation performance of ET<sub>SMAP</sub> and  
622 ET<sub>SMOS</sub> for savanna showed the greatest difference. In general, the ET<sub>SMAP</sub> and ET<sub>SMOS</sub> were slightly  
623 different, and the ET<sub>SMAP</sub> was more improved than ET<sub>SMOS</sub>.

624 Figure 10 (right) shows the assimilation accuracy of ET<sub>SMOS</sub> and ET<sub>SMAP</sub> in different humid and arid  
625 regions. The ET<sub>SMAP</sub> had significant advantages for the four indicators. The R<sup>2</sup> of ET<sub>SMAP</sub> was higher than  
626 that of ET<sub>SMOS</sub> in all the areas. However, ET<sub>SMOS</sub> in some evaluation indicators showed a better  
627 performance than ET<sub>SMAP</sub> (BIAS in the humid region; ubRMSD in the sub-dry humid region). This may  
628 be due to the overall more humid nature of SMOS ~~S~~SM than the SMAP ~~S~~SM. Moreover, the sensitivity  
629 of deep soil moisture contributed more to the ET in humid areas than in the water-limited areas.

630 *4.4. Global simulations of GPP and ET with joint assimilation of LAI and soil moisture data*

631 To assess the spatial scalability of the LPJ-VSJA assimilation scheme, we simulated the global daily  
632 GPP and ET for 2010–2018 with a spatial resolution of 0.25°. The original results simulated by the LPJ-  
633 DGVM and LPJ-VSJA were referred to as LPJ-DGVM GPP(ET) and LPJ-VSJA GPP(ET), respectively.  
634 We compared the annual spatial GPP and ET values and the error standard deviation of the LPJ-VSJA  
635 with several existing flux products.

636 Figures 11 and 12 depict the spatial distribution of the annual mean and the differences between our  
637 simulation results and the global independent satellite-based products. The developed LPJ-VSJA GPP  
638 was the closest to GOSIF GPP (Li and Xiao 2019) in most regions with the lowest spatial mean deviation  
639 (LPJ-VSJA-GOSIF) ( $27.9 \text{ g C m}^{-2} \text{ yr}^{-1}$ ), followed by GLASS GPP ( $51.2 \text{ g C m}^{-2} \text{ yr}^{-1}$ ) (Yuan et al. 2010),  
640 LPJ-DGVM ( $-73.4 \text{ g C m}^{-2} \text{ yr}^{-1}$ ), and MODIS GPP ( $93.1 \text{ g C m}^{-2} \text{ yr}^{-1}$ ). LPJ-VSJA had higher GPP values  
641 than GOSIF GPP in tropical regions, such as Amazonia, Central Africa, and Southeast Asia. In general,  
642 the annual mean and differences between MODIS, GOSIF GPP, LPJ-DGVM, and our LPJ-VSJA were  
643 in broad agreement (with higher  $R^2$  ranging from 0.74 to 0.95).

644 LPJ-VSJA ET was the closest to GLEAM ET on the spatial average with the least spatial average  
645 deviation ( $-13.9 \text{ mm yr}^{-1}$ ) and highest  $R^2$  (0.88), followed by GLASS ET ( $-23.1 \text{ mm yr}^{-1}$  and 0.82), GLDAS  
646 ET ( $-34.7 \text{ mm yr}^{-1}$  and 0.73), LPJ-DGVM ( $-48.7$  and  $0.66 \text{ mm yr}^{-1}$ ), and MODIS ET ( $-122.1$  and  $0.54 \text{ mm}$   
647  $\text{yr}^{-1}$ ).

648

649 **Figure 11. Column A: Spatial distribution of annual LPJ-VSJA GPP and other independent satellite-based**  
 650 **datasets (a: MODIS GPP; b: GLASS GPP; c: GOSIF GPP; e: LPJ-DGVM). Column B: Spatial**

660

661 Figure 13 (a)–(e) represent the spatial error standard deviation ( $\sigma$ ) distribution of MODIS, GLASS,  
662 GOSIF, and LPJ-VSJA GPP, respectively. The graphs on the right side depict the corresponding  
663 histograms. The  $\sigma$  of the MODIS GPP was evenly distributed between 30 and 60 g C m<sup>-2</sup> month<sup>-1</sup>, while  
664 the average  $\sigma$  of other products was concentrated in 0–20 g C m<sup>-2</sup> month<sup>-1</sup> (90%). The high errors of all  
665 products were concentrated in the high temperature and humid areas of southern North America, eastern  
666 South America, humid and dry sub-humid areas of South Asia, and the savannas of Africa and Australia.  
667 The error histogram of GOSIF GPP and LPJ-DGVM GPP were in line with the normal distribution, with  
668 an average value of 8.3 g C m<sup>-2</sup> month<sup>-1</sup> and 22.4 g C m<sup>-2</sup> month<sup>-1</sup>. The GLASS GPP product had the  
669 lowest mean value (3.6 g C m<sup>-2</sup> month<sup>-1</sup>), followed by LPJ-VSJA (4.7 g C m<sup>-2</sup> month<sup>-1</sup>), but the error  
670 variance of the LPJ-VSJA product was the lowest, indicating a stability of the regional error (Table S4).  
671 Compared to the LPJ-DGVM, the joint assimilation results showed improvement in all regions (the  
672 average error reduced by 17.7 g C m<sup>-2</sup> month<sup>-1</sup>), especially in the humid regions of South Asia, Australia,  
673 and the United States. Our LPJ-VSJA GPP was generally proven to have high accuracy and stability for  
674 spatial analysis and could provide a reference for other model products.

**Figure 13. Spatial distribution and histograms of error standard deviation ( $\sigma$ ) for global GPP products: MODIS (a), GOSIF (b), GLASS (c), LPJ-DGVM (d), and LPJ-VSJA (e).**

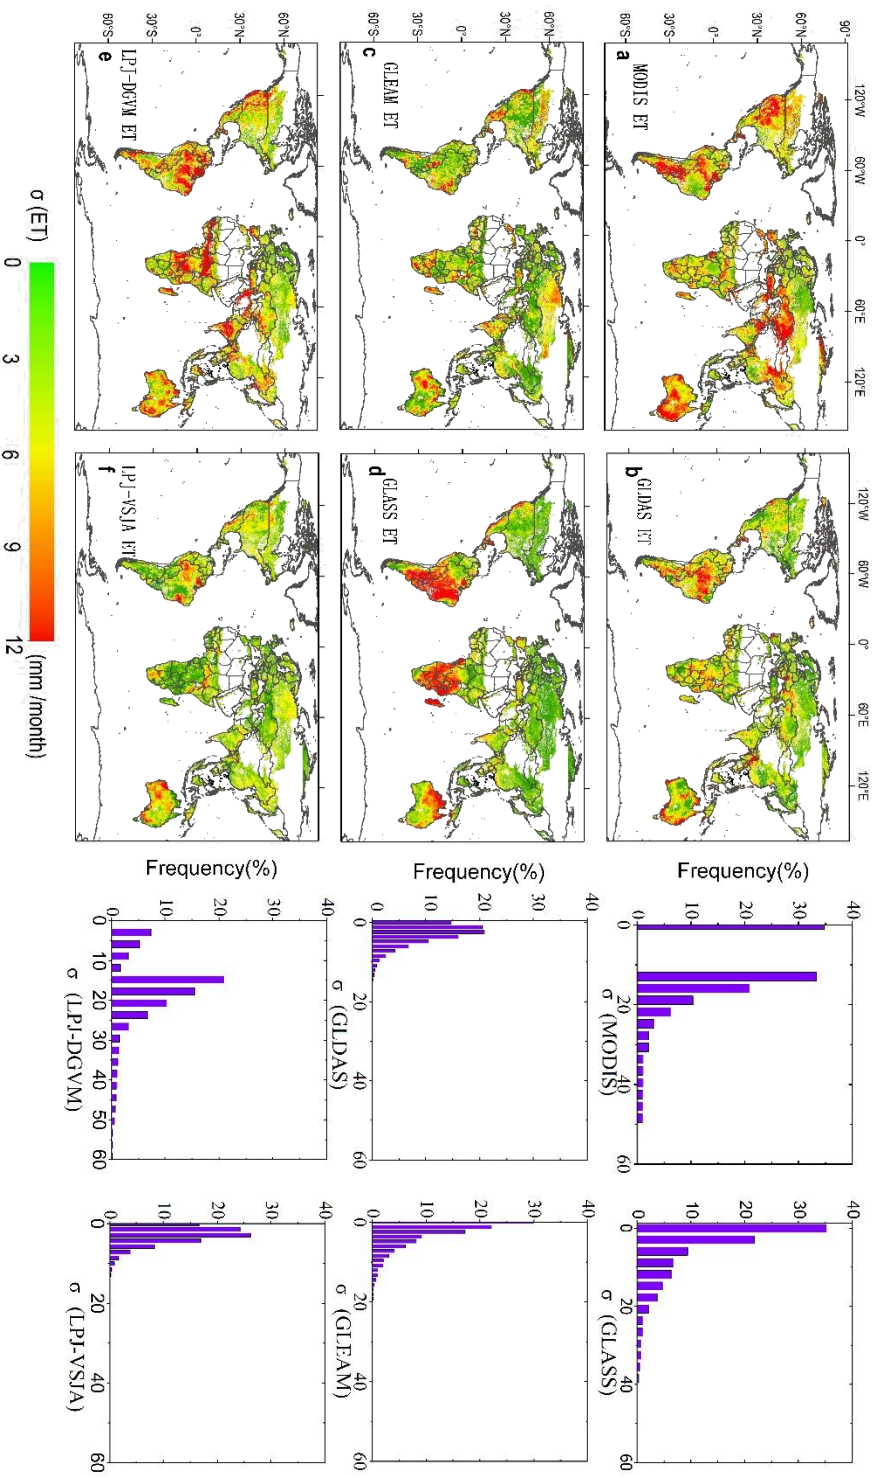

Figure 14. Spatial distribution and histograms of error standard deviation ( $\sigma$ ) for global ET products:

MODIS (a),GLDAS (b),GLEAM (c), GLASS (d), LPJ-DGVM (e), and LPJ-VSJA (f).

677        Figures 14 (a)–(f) show the  $\sigma$  of MODIS, GLDAS, GLEAM, GLASS, and LPJ-VSJA ET (the units  
678 are mm/month), and the right graphs are the corresponding histograms. The  $\sigma$  values of GLDAS and LPJ-  
679 VSJA represented a normal distribution trend. Except for MODIS, GLASS, and LPJ-DGVM (0–60 mm  
680 month<sup>-1</sup>), the  $\sigma$  of other products was generally between 0-20 mm month<sup>-1</sup>. The simulation error was  
681 relatively smaller in the Northern Hemisphere than in the Southern Hemisphere, especially for GLASS  
682 ET and GLDAS ET. Significant improvements in joint assimilation were observed in the northern  
683 hemisphere (especially in the semi-arid areas of the western United States and savanna and cropland areas  
684 of central India) and African savanna areas, and the average error was reduced by 15.1 mm month<sup>-1</sup>. In  
685 general, the error mean and variance of LPJ-VSJA and GLEAM products were relatively low (Table S4),  
686 and there was no apparent extremely high value region in the error distribution. Among the five products,  
687 LPJ-VSJA had the lowest error mean and variance and the highest accuracy.

## 688 **5. Discussion**

### 689 *5.1 Advantage of joint assimilation for GPP and ET*

690 The benefit of employing multiple data flows in an assimilation system is the complementarity of  
691 the data, which enables constraints on different components of the underlying process-based terrestrial  
692 biosphere model. Due to the interaction and feedback between the internal components of the model, the  
693 assimilation of multiple observations has a synergistic effect, and the integrated constraints are greater  
694 than the individual constraint (Kato et al. (2013)). The advantage of our joint assimilation is that it can  
695 improve the simulation accuracy of both GPP and ET, especially ET, in arid and semi-arid regions.

696 In the GPP assimilation experiment, the performance of the LAI assimilation was better than that of  
697 the SSM assimilation possibly for two reasons: (1) the LPJ-VSJA is more controlled by LAI data because  
698 the ratio of assimilated LAI (daily input) to SSM observations (3-day interval input) is approximately 3:1,  
699 which makes the likelihood function biased to LAI data; (2) the SM directly influences the simulation of  
700 ET, and the corresponding time function (computes the top layer SM (50 cm)) used here by Zhao et al.  
701 (2013) will result in the error of the updated top SM and propagating the error to the  $GPP_{SM}$ . In addition,  
702 the 8-day interval LAI has the capability to capture the temporal variability of phenology.

703 Current studies on terrestrial water and carbon flux assimilation mostly focus on the assimilation  
704 between a single model framework and observation results, lacking the fusion and comparison between  
705 multiple models. The processed models used in DA are simplifications and approximations of reality, and  
706 different models focus on different ecological processes. In this study, the updated ET module was

707 integrated to compensate for the simplification of soil stratification and the lack of SM information in the  
708 hydrological module of the LPJ-DGVM. Therefore, the integration of multiple types of models and multi-  
709 source observation data (remotely sensed data, ecological inventory data (National Ecological  
710 Observatory Network, NEON (Keller et al. 2008)), and other measurements (Desai et al. 2011; Hayes et  
711 al. 2012) is expected to more objectively and effectively simulate the real state of ecosystems.

## 712 *5.2 Comparison of joint assimilation (LPJ-VSJA) and other models for GPP and ET across regions and* 713 *vegetation types*

714 Global GPP and ET for different products were calculated by multiplying the global mean GPP  
715 density flux with the global vegetation area (122.4 million km<sup>2</sup>) originated from the MODIS land cover  
716 product (Friedl et al. 2010). The mean global GPP of the LPJ-VSJA (130.2 Pg C yr<sup>-1</sup>) was  
717 approximately 12% lower than that of PML-V2 (145.8 Pg C yr<sup>-1</sup>) and 18% higher than that of GLASS  
718 and MODIS, respectively (Table S6). The GPP values of LPJ-VSJA and GOSIF were the most similar.  
719 The GOSIF GPP was developed from gridded SIF using simple linear relationships between SIF and  
720 GPP. Our global LPJ-VSJA GPP estimates were within the currently most plausible 110–150 Pg C/yr  
721 range.

722 As for ET, our results were similar to those of GLEAM ET and lower than those of PML-V2,  
723 GLDAS-2, and GLASS ET (~72000 ~~mm~~ km<sup>2</sup> yr<sup>-1</sup>). Joint assimilation improved the overestimation of  
724 LPJ-DGVM ET. At the daily scale, the estimation accuracy of PML-V2 and GLDAS-2 products,  
725 calibrated with flux tower data, was better than that of our estimates, which suggests an underestimation

726 of LPJ-VSJA ET in wet regions. It is likely because the SSM of SMAP or SMOS was underestimated in  
727 the wet region or the influence of deep SM was under-represented. According to Seneviratne et al. (2010),  
728 satellite-based ET estimation approaches often overestimate ET in areas of arid and semi-arid climatic  
729 regimes in the magnitude of 0.50 to 3.00 mm d<sup>-1</sup>. The poor performance of these models can largely be  
730 attributed to the lack of constraints of SSM or RZSM and more accurate vegetation parameters (Gokmen  
731 et al. 2012; Pardo et al. 2014). For instance, the monthly estimated ET modeled by the Penman-Monteith-  
732 Leuning (PML) model agreed with flux tower data well ( $R^2 = 0.77$ ; BIAS<sub>bias</sub> = - 9.7%, approximately  
733 0.2 mm d<sup>-1</sup>). Our annual ET simulations were lower than other products and slightly underestimated tower  
734 ET with a BIAS<sub>bias</sub> of 0.19 mm d<sup>-1</sup> ( $ET_{OBS} - \frac{ET_{joint} - ET_{co}}{ET_{joint}}$ ).

735 In general, GPP and ET had better assimilation performance in arid and semi-arid regions than in  
736 humid and sub-dry-semi-humid regions likely because of the following reasons. First, the incorporation  
737 of surface-SSM is more important for vegetation growth in water-limited areas. The module PT-JPL<sub>SM</sub>  
738 has been proven to have better performance in semi-arid and arid regions (Purdy et al. 2018). Our  
739 integrated model LPJ-PM also performed better in semi-arid and arid regions by assimilating SMAP soil  
740 moisture (Li et al. 2020). Second, the input performance, including SMOS and SMAP SSM products, is  
741 better in arid and temperate regions than in cold and humid regions (Zhang et al. 2019). Third, the  
742 vegetation types in humid regions are more complex and relatively less accurately simulated by the LPJ-  
743 DGVM within a single grid cell. For comparison, Zhang et al. (2020) used a data-driven upscaling  
744 approach to estimate GPP and ET in global semi-arid regions. This data-driven approach ( $R^2 = 0.79$ ,  
745  $RMSD = 1.13 \text{ g C m}^{-2} \text{ d}^{-1}$ ) had slightly higher performance in estimating GPP than our LPJ-VSJA ( $R^2$

746 =0.73 and RMSD= 1.14 g C m<sup>-2</sup> d<sup>-1</sup>) and the data-driven method (R<sup>2</sup> = 0.72 and RMSD = 0.72mm d<sup>-1</sup>)  
747 had identical performance for estimating ET with our LPJ-VSJA( R<sup>2</sup> =0.73 and RMSD= 0.72 mm d<sup>-1</sup>).

748 Our assimilation performance varied with PFT. The GPP and ET assimilation results of savanna sites  
749 performed well in both dry and wet regions, and those of shrubland sites showed the most remarkable  
750 improvement for simulations of LPJ-DGVM. The original simulation and assimilation performance of  
751 grassland sites in the semi-arid and arid regions were the best for all five PFTs. Consistent with our  
752 research, previous studies also showed better GPP or ET simulations for grassland, savannas, and  
753 shrublands biomes. For instance, Feng et al. (2015) validated five satellite-based ET algorithms for semi-  
754 arid ecosystems and concluded that all the models produced acceptable and relatively better results for  
755 most grassland, savanna, and shrubland sites. Yang et al. (2017) demonstrated that the GLEAM ET had a  
756 superior performance for the grassland sites. The GOSIF GPP demonstrated better simulation for  
757 grassland and woody savannas sites at 8-day time steps with higher R<sup>2</sup> (0.77 and 0.83, respectively) and  
758 lower RMSD (1.48 g C m<sup>-2</sup> d<sup>-1</sup> and 1.1 g C m<sup>-2</sup> d<sup>-1</sup>) (Li and Xiao 2019). In contrast, our LPJ-VSJA GPP  
759 showed an R<sup>2</sup> of 0.87 for grassland and 0.75 for savannas and an RMSD of 1.11 g C m<sup>-2</sup> d<sup>-1</sup> and 1.1 g C  
760 m<sup>-2</sup> d<sup>-1</sup>, respectively, in semi-arid and arid regions.

### 761 *5.3 Uncertainty analysis of joint assimilation*

762 Our validation results at both site and regional scales indicated that uncertainty existed in LPJ-VSJA  
763 daily GPP and ET estimates. The errors from the tower EC observations, model-driven data, model  
764 structure, error of satellite-based observations (e.g., LAI and SSM), and the spatial scale mismatch

765 between the ground observed footprint size and satellite-derived footprint size were the vital factors  
766 affecting assimilation performance.

767 First, recent studies have revealed errors in the GLASS LAI and SMOS or SMAP SSM compared  
768 with ground measurements. By computing the RMSD and  $R^2$  of each product, the GLASS LAI accuracy  
769 was clearly superior to that of MODIS and Four-Scale Geometric Optical Model based LAI (FSGOM) in  
770 forests and GLASS and FSGOM led to in much higher annual GPP and ET estimates compared to  
771 MCD15(Liu et al. 2018). The vegetation type (or land cover) misclassification caused 15–50% differences  
772 in LAI retrieval (Fang and Liang 2005; Gonsamo and Chen 2011). Yan et al. (2016) calculated a RMSD  
773 of 0.18 for the GLASS LAI over a range of HeiHe riverdrainage basin sites and used the error to improve  
774 the simulation of LAI and fluxes by assimilating GLASS LAI data. Previous studies reported an  
775 improvement in the performance of the SMOS and SMAP products (Lievens et al. 2015; Miernecki et al.  
776 2014), which both provide an accuracy of  $0.04 \text{ m}^3 \text{ m}^{-3}$  (Zhang et al. 2019). However, the actual  
777 observation error of these two products typically depends on the spatial location and time of the year  
778 (RMSD varying between 0.035 and  $0.056 \text{ m}^3 \text{ m}^{-3}$  for several retrieval configurations) (Brocca et al. 2012).  
779 According to Purdy et al. (2018), the ET simulated by PT-JPL<sub>SM</sub> using the 9 km SM\_L3\_P\_E data showed  
780 an inferior agreement ( $R^2= 0.47$ ) but a relatively low RMSD ( $0.77 \text{ mm d}^{-1}$ ), due to the SMAP errors in  
781 the grid cell with soil heterogeneity and the climatological differences between model SM forecasts and  
782 SMAP SSM (Reichle and Koster 2004). We rescaled the  $ET_{PM}$  to the probability distribution of the  $ET_{LPI}$   
783 through a cumulative distribution function (CDF) to correct the potential seasonal biases of  $ET_{PM}$  before  
784 assimilation.

785 Second, there is large uncertainty in the influence of ~~root-zone-SM~~RZSM as the source of water  
786 available to plants (Albergel et al. 2008; Bonan et al. 2020). Our GPP results of irrigated sites~~cropland~~  
787 ~~sites~~ were largely influenced by US-Ne1, an irrigate site. This site maintained high annual GPP in 2012  
788 despite the drought (Figure S4S8). However, the SMOS SSM in 2012 had a lower ~~surface-S~~SSM annual  
789 mean than the site observations likely because the detected soil layer (0-50 cm) of the site observation is  
790 deeper than that of the satellite retrieval and the cumulative deep soil moisture due to the regular irrigation  
791 was higher than the ~~surface-S~~SSM that could easily be vaporized during the drought period (Figure S4S8).  
792 Therefore, the influence of deep SM of some cropland sites during the drought years induced large  
793 simulation errors and unsatisfactory assimilation performance. Moreover, some deep-rooted forests  
794 maintain a high LAI during drought by absorbing deep SM (>2 m) and groundwater (Zhang et al. 2016).  
795 Thus, joint assimilation of the LAI and SSM may eliminate a portion of the underestimation of GPP of  
796 such vegetation in drought periods. Therefore, further research is needed on how to optimally utilize  
797 satellite SM data for improving GPP and ET simulations.

798 Third, the problem of mixed pixels and mismatches in the observation footprints may also have an  
799 influence on the accuracy of estimated GPP and ET. The 5 km spatial resolution of the GLASS LAI ,9  
800 km of SMAP, and 25 km of SMOS products cannot capture the sub-grid-scale condition, especially in  
801 grid cells for complex land surfaces or strong soil heterogeneity. To ensure the consistency of the grid-  
802 cell representativeness for the LAI and SSM, the interpolation result in errors that propagate through the  
803 modeling and assimilation, causing the accumulation of output errors (Nijssen and Lettenmaier 2004).  
804 Moreover, the shrubland in the LPJ-DGVM was most likely simulated as C4 grassland in the

805 hydrothermal condition of semi-arid and arid regions. In contrast, the shrubland tended to be hybrid  
806 vegetation types (grassland mixed with other types of forest vegetation) in the hydrothermal condition of  
807 humid and sub-dry humid regions, and the simulated canopy height is closer to the real condition of  
808 shrubland. This might also be the reason for the superior performance of  $ET_{LPJ}$  and assimilation results  
809 of shrubland sites in humid and sub-dry humid regions.

810       When assimilating multiple data streams, all data streams could be in the same optimization  
811 (simultaneous assimilation) or use a sequential (step-by-step) approach. Mathematically, simultaneous  
812 optimization is optimal because strong parametric connections are maintained between different  
813 processes. However, complications may arise due to computational constraints related to the inversion of  
814 large matrices or the requirement of numerous simulations, particularly for global datasets (e.g. Peylin et  
815 al.,2016), and due to the “weight” of different data streams in the optimization (e.g. Wutzler and  
816 Carvalhais, 2014). This is particularly true when considering a regional-to-global-scale, multiple site  
817 optimization of a complex model that contains many parameters, and which typically takes on the order  
818 of minutes to an hour to run a one-year simulation. In practice, it is very difficult to define a probability  
819 distribution that properly characterizes the model structural uncertainty and observation errors accounting  
820 for biases and non-Gaussian distributions. Nevertheless, a step-wise assimilation may be useful in dealing  
821 with possible inconsistencies on a temporary basis, since parameter error covariance matrix must be  
822 propagated at each step. It’s worth noting that the deviation between the model and observational data  
823 should be solved in the process of step-wise assimilation, such as the joint assimilation in this study, the  
824 satellite observations and model simulation were fitting through the CDF method so that the first step

825 assimilation will strongly constrain the uncertainty of parameters related to phenology and carbon flux  
826 and propagate to the second step . Alternative solutions were found for water -related parameters through  
827 soil moisture, providing a better fit for all data streams. The sequence of assimilation is essential in the  
828 step-wise assimilation, and if the first observation contains a strong BIAS~~bias~~, then the associated error  
829 correlation will also propagate through the first assimilation. If the autocorrelation in the observation error,  
830 or the correlation between the data stream errors is not considered, it is likely that the posterior simulation  
831 has been overturned. That is, we overestimate the reduction in parametric uncertainty. If two observational  
832 data are less uncertainty (i.e., high precision of observation data), and the model of deviation is smaller  
833 (depend on the spatial scale and inversion method). Moreover, the correlation of these observations is  
834 stronger, and contain enough spatio-temporal information to limit all the parameters optimization  
835 accurately, the step-wise assimilation performance is basically the same as that of simultaneous  
836 assimilation.

## 837 **6. Conclusions**

838 We developed an assimilation system LPJ-VSJA that integrates GLASS LAI, SMOS SSM, and  
839 SMAP SSM data to improve GPP and ET estimates globally. The system was designed to assimilate two  
840 SSM products (SMOS and SMAP) into the integrated model - LPJ-PM for both dry and humid regions  
841 through separate and joint assimilation. The results show that the joint constraints provided by vegetation  
842 and soil variable strategies improve model simulations. Both the original and joint assimilation results for  
843 GPP and ET in semi-arid and arid regions performed better than those in humid and ~~dry-sub~~sub-dry humid

844 regions, and the LPJ-PM that emphasized the SSM information is more suitable for the water-limited  
845 regions. For ET assimilation, the different SSM products influence assimilation performance, and SMAP  
846 SSM possesses a slight advantage in most vegetation types and in both dry and humid regions. Our global  
847 LPJ-VSJA GPP and ET products have relatively higher accuracy than other products, especially in water-  
848 limited regions with lower ET values.

#### 849 **Data availability**

850 The LPJ-DGVM v4.1 version code (LPJ-ML) and example configurations are public available via the  
851 project homepage (<https://github.com/PIK-LPJmL/LPJmL>). We used the 3.01 version of LPJ-DGVM,  
852 which removed the agricultural management module. The access of all the input and validation dataset of  
853 assimilation system have been described in article. The assimilation method code configured by Fortran  
854 platform could be provided by contacting the X.T co-author. The modified code of LPJ-PM model and  
855 the underlying and global LPJ-VSJA GPP and ET data can be obtained by contacting the lead author of  
856 this manuscript.

#### 857 **Author contributions**

858 S.L. and L.Z. designed the experiment and wrote the paper with support from all coauthors. S.L. and R.M.  
859 implemented the codes necessary for the experiments. J.X. contributed to the structure of the article and  
860 comparison of assimilation performance between the SMOS and SMAP experiments. X.T provided the  
861 POD-En4DVAR method and the code. M.Y contributed to the validation and analysis of the results. All  
862 the authors contributed to the synthesis of results and key conclusions.

863 **Competing interests**

864 The authors declare that they have no known competing financial interests or personal relationships that  
865 could have appeared to influence the work reported in this paper.

866

867 **Financial support**

868 S.L., L.Z., R.M., and M.Y. were funded by the National Natural Science Foundation of China (Grant No.  
869 41771392; PI Li Zhang) and (Grant No. 41901364; PI Min Yan).
