8 **Abstract.** Adolf and Günther Thiem, father and son, left behind a methodological legacy that many current hydrogeologists  
9 are probably unaware of. It goes much beyond the Dupuit-Thiem analytical model for pump test analysis, which is connected  
10 to their name. Methods, which we use on a day-to-day basis today, such as isopotential maps, tracer tests and vertical wells  
11 were amongst the many contributions which the Thiems either developed or improved. Remarkably, this was not done in a  
12 university context but rather as a by-product of their practical work designing and building water supply schemes in countries  
13 all over Europe. Some of these water works are still active. Both Thiems were also great science communicators. Their  
14 contributions were read and applied in many countries, especially in the US, through a personal connection between Günther  
15 and O.E. Meinzer, the leading USGS hydrogeologist of the time.

17 **Keywords**

18 Adolf Thiem, Günther Thiem, O.E. Meinzer, history, pumping test, well construction

## 19 **1 Introduction**

20 The name Thiem appears in many hydrogeological textbooks, most often in the context of the Dupuit-Thiem method, an  
21 analytical model for the evaluation of steady-state pumping tests (e.g. Batu, 1998; Kruseman and de Ridder, 2000; Bear, 2007;  
22 Kresic, 2007; Kasenow, 2010). Few hydrogeologists, however, are aware that there were two engineers of this name, father  
23 and son, Adolf and Günther Thiem. Both contributed much more to the current hydrogeological methods than just a somewhat  
24 outdated pumping test model. Their work laid the foundations for a diversity of applications and methods still being used  
25 today, e.g., tracer tests, well construction, and isopotential maps, and was widely acknowledged even on the international scale,  
26 especially in the US. They also planned and supervised the construction of many groundwater supply schemes in several  
27 European countries, some of which are still active today, although in modernized form. The focus of this study is thus to  
28 investigate the scientific biography of both Thiems and how their contributions found their way into the international canon of  
29 methods.

## 31 **2 Adolf Thiem**

### 32 **2.1 Biography**

33 Adolf Thiem was born on February 21, 1836, under the full name of Friedrich Wilhelm Adolf Thiem in the town of Liegnitz  
34 (now Legnica, Poland) in the Prussian province of Silesia, where he obtained his high school diploma (Herfried Apel, pers.  
35 comm.; Anonymous, 1906). His family had been living in Liegnitz at least since the 18<sup>th</sup> Century. His father was the  
36 eponymous Friedrich Wilhelm Adolf Thiem (born 1804), who married Johanna Natalie Julianne Thiem, nee Küpper in 1835.  
37 The family was of a craftsman background, but all were self-employed; the father was a master plumber, the grandfather  
38 Gottlieb Wilhelm a master nail smith, and the great-great-grandfather Johann a master cartwright. Adolf had a younger brother,  
39 Paul Thiem (born 1841 in Liegnitz, died 1883 in Munich), who also became an engineer. Adolf left his parents' house at the  
40 age of 14 for apprenticeship and self-study (Vieweg, 1959). He never attended a university but became an autodidact. At the  
41 age of 25, he published his first paper in the influential *Journal für Gasbeleuchtung* (Thiem, 1861), where he introduces himself  
42 as an inspector at the gas works of his hometown Liegnitz, a job he still held at least into the following year (Thiem, 1862). In  
43 his 1863 paper in the same journal, he signs as inspector of the gas works of the much larger town of Munich (Thiem, 1863),  
44 a job he kept until 1865. The early papers already show his mathematical proficiency and his will to improve technical concepts  
45 (Thiem, 1861, 1864, 1866). Through contact with Nicolaus Schilling (1826-1894), founder of the now renamed *Journal für*  
46 *Gasbeleuchtung und Wasserversorgung* (Journal for gas lighting and water supply, based in Munich), he was recommended  
47 to Heinrich Gruner (1833-1906), a German engineer based in Basel, Switzerland, at that time. Gruner had mainly built gas  
48 works so far but wanted to expand into the water supply market and hired Thiem as an assistant in 1865 (Mommsen, 1962).  
49 Gruner introduced the aspiring Thiem to some fundamental French literature, including the works by Henry Darcy (1856) and  
50 Jules Dupuit (1854, 1863). His first work assignments led Thiem to the French town of Beaucourt, near Belfort, where he built  
51 spring captures and pipelines, and to Winterthur, Switzerland. After a bumpy start, Thiem proved to be an excellent technician,  
52 and in 1868 Gruner made him his partner and head of the branch office in Dresden (Mommsen, 1962). The company was  
53 called "Heinrich Gruner & Thiem, Ingen. und Unternehmer von Wasseranlagen" (Engineers and entrepreneurs of water  
54 schemes). Thiem was mainly tasked with obtaining a share of the quickly expanding market for water supply in Germany.  
55 Again, after a bumpy start, Thiem managed to acquire several contracts, mainly convincing his clients through his technical  
56 competence. One of the projects was for the historic mining town of Freiberg, Saxony, where he installed a dual system in  
57 1871, consisting of separate spring-fed drinking water and a service water network (Grahn, 1883, 1902). Gruner, however,  
58 was not equally happy since Thiem showed much less enthusiasm for financial issues and the day-to-day supervision of the  
59 construction sites than for the technical details. Therefore, he decided to move to Dresden himself in 1873 to regain control  
60 (Mommsen, 1962). Together, they designed and built the water supply schemes for the cities of Zwickau (1875) and  
61 Regensburg (1875), both fed by springs. For the latter, they relocated their company to this town in 1874. In the newspaper

62 announcements from this time, Thiem is mentioned as “Ingenieur von Kamburg, Sachsen-Meiningen” (engineer from the city  
63 of Kamburg, Duchy Saxony-Meiningen), where he must have lived briefly. The Regensburg scheme was a technical challenge  
64 since it involved capturing springs located in a river bed, which needed to be protected from the river water itself. Additionally,  
65 the pipeline had to be laid through the bed of the Danube and Regen Rivers, which they accomplished by the intensive use of  
66 divers (Thiem, 1877; Mommsen, 1962). It was not unusual that such projects were financed by issuing stock for a designated  
67 public water supply company, in this case with a value of 1,028,400 German Mark, of which the Gruner & Thiem company  
68 assumed a substantial share of 340,000 Mark (Grahn 1902). The project was so time-consuming that Thiem moved his family  
69 to Regensburg. He had married Luisa Thekla Groß (born 1852 in Zöblitz, died 1931 in Leipzig) in 1871 in Freiberg, while  
70 working there. All his three children were born in Regensburg: Paul Adolf (1874-1907), Ernst Gerhard Günther (1875-1959)  
71 and Katharina Else (1876-?) (Mommsen, 1962; Hoffmann, 2017). Gruner and Thiem’s first truly groundwater-based supply  
72 system was the one for the city of Augsburg (1873-1879). Groundwater head observations for this study were already plotted  
73 in the form of an isopotential map.

74

75 **Figure 1: Adolf Thiem around the year 1900 (Franke and Kleinschroth, 1991).**

76

77 Pumping tests, using observation wells to investigate the aquifer response, were already performed by the German engineer  
78 Bernhard Salbach (1833-1894) in Halle, Germany, in 1866 (Houben, 2019). Thiem’s significant improvement, first applied in  
79 Augsburg, was the comparison of the drawdown to predictions by the Dupuit-Thiem model, which he had published previously  
80 (Thiem, 1870, see below). This was probably the first pumping test subjected to a rigorous mathematical evaluation. Another  
81 pumping test in Strassburg, Alsace, received more attention since its results were published in much more detail (Thiem,

82 1876b). Through their work in Augsburg and Strassburg, Thiem had clearly set the standard for identifying and quantifying  
83 groundwater resources. But he also considered the basic engineering problems of water supply, e.g., the design of pipeline  
84 networks (Thiem, 1876a, 1883a, 1884a, 1885b,c, 1915).

85

86 The conflicts between Gruner and Thiem had not abated. Thiem considered himself the underappreciated and underpaid  
87 workhorse, and in 1876 the partnership was dissolved (Mommsen, 1962). Both, independently of each other, moved to Munich,  
88 where several concepts for a central water supply were being considered. Thiem favoured groundwater, based on an intensive  
89 investigation in the fluvial Gleisenthal aquifer and published a detailed report (Thiem, 1878). In the end, the city council  
90 selected a concept proposed by Bernhard Salbach, based on karst springs located 38 km away in the Alps, due to their high  
91 yield, pristine water quality, and the fact that the system was purely gravitational. This proved to be a wise decision since the  
92 system is still the backbone of the city's water supply today. After the split from Gruner, Thiem successfully promoted himself  
93 by advertising the projects with Gruner as his own exploits. An irate Gruner felt obliged to publish a piece in a Munich  
94 newspaper, denouncing Thiem as a mere assistant, whose responsibility had been to travel, acquire projects, take  
95 measurements, and prepare calculations, which then had to be submitted to Gruner (Gruner 1876).

96

97 In 1886, following an invitation by the city mayor Otto Georgi, Thiem moved for the last time to Leipzig. In the first year,  
98 they lived in the Kramerstraße but then moved into the newly built "Haus Pommer" at Hillerstraße Nr. 9 in 1887, which was  
99 to become the Thiem family residence at least until the late 1950s. His consulting company, which at the turn of the century  
100 figured as "A. Thiem & Söhne, Civilingenieure" (A. Thiem & sons, Civil engineers, Mommsen, 1962) became so successful  
101 that he had to rent a separate office already in 1891, located at the Thomaskirchhof 18, right in the city centre, which he later  
102 moved to Quaistraße 2 in 1902 (today Carl-Maria von Webern-Straße). The company employed up to twelve people, including  
103 his two sons. His older son Paul Adolf, a graduated civil and mechanical engineer died in December 1907, aged only 33, a few  
104 months before Adolf (Anonymous, 1908). Adolf Thiem was the leading planner of the groundwater supply scheme for several  
105 larger cities (Table 1), including his new hometown Leipzig, which was expanded in several stages (Thiem, 1881, 1906, 1908).

116 Table 1: Main water supplies planned and built by Adolf Thiem (English names in parentheses)

Name of city	Name of city today	Comment	References
Freiberg		1871, with Gruner	Grahn (1883, 1902)
Zwickau		with Gruner	Grahn 1902, Mommsen (1962)
Regensburg		with Gruner	Thiem (1877a)
Augsburg		with Gruner	Gruner and Thiem (1874), Mommsen (1962)
Strassburg	Strasbourg, France	then Germany	Thiem (1876)
München (Munich)		not built	Thiem (1877b, 1880d, 1914)
Nürnberg (Nuremberg), also Fürth			Thiem (1879a, 1881a)
Riga		then Russia, today Latvia	Salm (1893), Thiem (1883b, 1888e)
Leipzig			Thiem (1881b,e,e 1883c, 1885a, 1889, 1890a, 1890b, 1891, 1892a, 1892b, 1906, 1908, 1911)
Gera			Thiem (1884c), Grahn (1902)
Stralsund		not built	Thiem (1888d)
Malmö, Sweden		1890, with J.G. Richert	Svensson (2013)
Potsdam			Thiem (1892d)
Charlottenburg		now part of Berlin	Thiem (1897a, 1913a)

Mainz		incl. Laubenheim	Thiem (1897b,c), Grahn (1902)
Dessau		1897	Grahn (1902), Pfeffer (1906)
Breslau	Wrocław, Poland	then Germany	Anonymous (1902)
Prag (Prague)	Praha, Czech Republic	then Austria-Hungary	Anonymous (1903)
Braunschweig (Brunswik)			Grahn (1902), von Feilitzsch (1904)
Waldenburg	Wałbrzych, PL	then Germany	Lummert (1905)
Landeshut	Kamienna Góra, PL	then Germany	Thiem (1909)

117

118 Other cities in Germany he was working for include – in alphabetical order - Biebrich, Blasewitz, Crimmitschau, Eilenburg,  
119 Essen, Frankenstein (Ząbkowice Śląskie, PL), Greifswald, Harburg/Hamburg, Hirschberg (Jelenia Góra, PL), Hohenstein,  
120 Kiel, Liegnitz (Legnica, PL), Limbach, Magdeburg (Thiem & Fränkel 1902), Mansfeld, Markranstädt, Meerane, Metz,  
121 Mittweida, Oels (Oleśnica, PL), Plauen, Posen (Poznan, PL), Warmbrunn (Cieplice Śląskie-Zdrój, PL), Wismar and Zeitz  
122 (Grahn 1902; Anonymous, 1906; Dyck, 1986). His expertise was also valued abroad (Anonymous, 1906, 1952; Dyck, 1986)  
123 and, additional to the entries in Table 1, led him to work in Romania (Bucharest, Czernowitz, Klausenburg/Cluj-Napoca),  
124 Scandinavia (Åbo/Turku, Finland, Malmö (Sweden), and Porto Alegre (Brazil). His work was not restricted to studies of  
125 aquifers and wells but also encompassed the hydraulics of pipeline networks, the improvement of pumps, the development of  
126 water treatment techniques (especially iron removal) and even the construction of water towers, e.g. the still existing tower in  
127 Strasbourg from 1878, the first with a semi-spherical wrought iron tank (Thiem, 1876, 1877a, 1878, 1880c, 1883a, 1884a,  
128 1885b, 1896, 1897a, 1894b, 1898b, 1915, 1929q; Grahn and Thiem, 1885). He briefly worked on inland navigation, in  
129 particular on the hauling of cargo vessels, on the Hohensaaten-Spandau canal near Berlin, work that was presented in a  
130 conference in Paris in 1892 (Thiem 1892c). Curiously, his home base is given as Eberswalde. He offered his clients the full  
131 package, ranging from groundwater exploration to planning and construction of wells and pipeline networks, water treatment  
132 plants and storage tanks, including economic considerations (Thiem, 1884b). He was probably one of the first to use the term  
133 “sustainability” (Nachhaltigkeit) in the context of groundwater (Thiem, 1881a). He had observed the groundwater levels in  
134 observation wells located along the Leipzig-Grimma train track over the course of 15 years. The relatively stable drawdowns  
135 led him to the conclusion that the drawdown caused by the extraction for the Leipzig water supply had become stable and  
136 extraction was thus sustainable (Thiem, 1881a).

137 In 1892, Thiem received the honorary title of “Königlich Sächsischer Baurat” (Royal Saxonian building officer). Probably in  
138 1899, he received the “Königlich Sächsischer Verdienst-Orden” (Royal Saxonian Order of Merit), as of 1900 he proudly added

139 the title “Ritter 2c” (knight, second class) to his entry in the Leipzig address book. A striking feature of his work ethic was that  
140 he never took out any patent, in order to foster the advancement of science (Anonymous, 1906, 1952). When asked about it by  
141 his pupils, he would smile and answer “Dies ist für die Allgemeinheit und nicht für mich alleine da. (This is for the public and  
142 not for me alone)” (Anonymous 1952). However, this claim is not entirely true since he took at least one patent on a water  
143 valve that would automatically close after a sudden pressure loss, e.g. caused by a pipeline rupture (Thiem, 1894a). On his  
144 70th birthday, he was honoured by a page-long biographical sketch in the Journal für Gasbeleuchtung und Wasserversorgung,  
145 which states his role as founding father of hydro(geo)logy (Anonymous, 1906). Adolf Thiem died after short but severe  
146 suffering at the age of 72 in Leipzig on May 2, 1908 (Anonymous, 1908). He was buried there on the Südfriedhof in an  
147 honorary grave that still exists (Fig. 2). It is only a few meters away from the still active Probstheida water works and its  
148 impressive water tower, which Thiem designed shortly before his death. In 1912, the city of Leipzig named a street after him  
149 (Thiemstraße), which still bears this name today and leads to the Probstheida water works (Fig. 2). Several important German  
150 hydrologists such as Emil Prinz, Max Rother and his son, Günther Thiem were his pupils. In Germany, his legacy was  
151 recognized and kept alive, evidenced by several commemorative articles (Thiem, 1929q; Prinz, 1936; Anonymous 1949;  
152 Anonymous 1952; Anonymous 1958; Vieweg 1958a,b, 1959; Dyck, 1986; Engemann, 1989). As late as 1956, his seminal  
153 1870 publication was reprinted (Thiem 1956).

154

155 Thiem’s contributions to the growing field of hydrogeology were also noted outside Germany, already during his lifetime. His  
156 work for the water supply of Leipzig was considered important enough to be presented at the world exhibition in Chicago in  
157 1893 (Hillger, 1893). In their 1899 book on groundwater flow, Franklin Hiram King and Charles Sumner Slichter cite seven  
158 of A. Thiem’s papers, including those on tracer tests and other German papers by Lueger and Hagen (King and Slichter, 1899).

163

## 164 **2.2 Contributions to pumping tests**

165 The analytical model describing the radial flow of groundwater to a well embedded in a horizontal circular island aquifer is  
166 sometimes called the Dupuit model after Jules Dupuit (1863), sometimes the Thiem model after Adolf Thiem (1870) or  
167 Günther Thiem (1906), and sometimes the Dupuit-Thiem model. It is therefore important to compare the seminal contributions.  
168 After analysis of open-channel flow, in chapter VIII of his 1863 publication, Dupuit turned his attention to flow in permeable  
169 soil (Du mouvement de l'eau travers les terrains perméables). Based on his work on open channel flow, Dupuit stated that the  
170 slope of a groundwater table should follow a parabolic equation of the type of Equation 1:

$$171 \quad i = \alpha \cdot Q + \beta \cdot Q^2 \quad (1)$$

172

173 Where  $i$  is the slope,  $Q$  is the flow rate, and alpha and beta are coefficients. This is basically identical to the later Forchheimer  
174 equation (Forchheimer, 1901). However, Dupuit realized that the velocity term  $\beta \cdot Q^2$  could be ignored due to the commonly  
175 very low flow velocities of groundwater. Assuming a radial symmetry and a horizontal aquifer, he then derived the fundamental  
176 equations describing groundwater flow to a well at steady state, for both water table and artesian aquifers. Thiem (1870) had  
177 clearly read Dupuit's paper, as he duly cites it and ends his paper with a literal quote in French from Dupuit. Günther Thiem  
178 claimed that his father had actually been a friend of Dupuit, which is technically possible since Dupuit died in 1876, well after  
179 the 1870 publication by Adolf (Thiem, 1951). There is, however, no other evidence that both knew each other, apart from  
180 Günther's claim. Thiem's paper follows parts of the outline of Dupuit's chapter VIII closely. So, was Thiem, just a copycat?  
181 Not quite! In his equations, Dupuit used two heights of the water table above the impermeable aquitard, (1)  $h_0$  in the well itself  
182 at the well radius  $r_0$  (la hauteur de l'eau dans le puit) and (2)  $H$  at the outer radius of the cone of influence (la hauteur de l'eau  
183 extérieure) at a radius  $R$  (le rayon du massif filtrant). While the choice of these two points was sufficient for the mathematical  
184 derivation, they both were a rather poor choice from a practical point of view. The water levels in the well were often affected  
185 by additional, non-laminar head losses caused by the well tubing itself, something which Dupuit was aware of (see below) but  
186 chose to ignore. He also gave no practical hints on how to obtain the outer limit. He only realized that the value for the outer  
187 radius is of limited influence as it appears in a logarithmic term ( $\log(R/r_0)$ ). As such, the equations were of limited practical  
188 use and were not taken up by practitioners.

189

190 It was Adolf Thiem's merit to have grounded the Dupuit equation in the real world. He used two observation wells located  
191 within the cone of depression at different radii  $r_1$  and  $r_2$ , thus avoiding the problems of turbulent losses in the well and of  
192 finding the radius of influence. While Dupuit (1863) takes precedence for the mathematical derivation (Ritzi and Bobeck,

193 2008), Thiem (1870) and his later papers (e.g. Thiem, 1876b) converted the method into a practical tool and popularized it. It  
194 is thus justified to call the method the Dupuit-Thiem model. Remarkably, his first-ever paper on groundwater became a classic.  
195 For the confined case, it takes the form of Equation 2:

$$196 \quad h_2 - h_1 = \frac{Q}{2 \cdot \pi \cdot K_{\text{aq}} \cdot B} \cdot \ln\left(\frac{r_2}{r_1}\right) \quad (2)$$

197 with

- 198  $h_1, h_2$  = head at radial distance  $r_1, r_2$  [L]  
199  $Q$  = pumping rate [ $\text{L}^3/\text{T}$ ]  
200  $K_{\text{aq}}$  = hydraulic conductivity [ $\text{L}/\text{T}$ ]  
201  $B$  = constant thickness of confined aquifer [L]  
202  $r_1, r_2$  = radius from well axis, with  $r_1 < r_2$  [L]

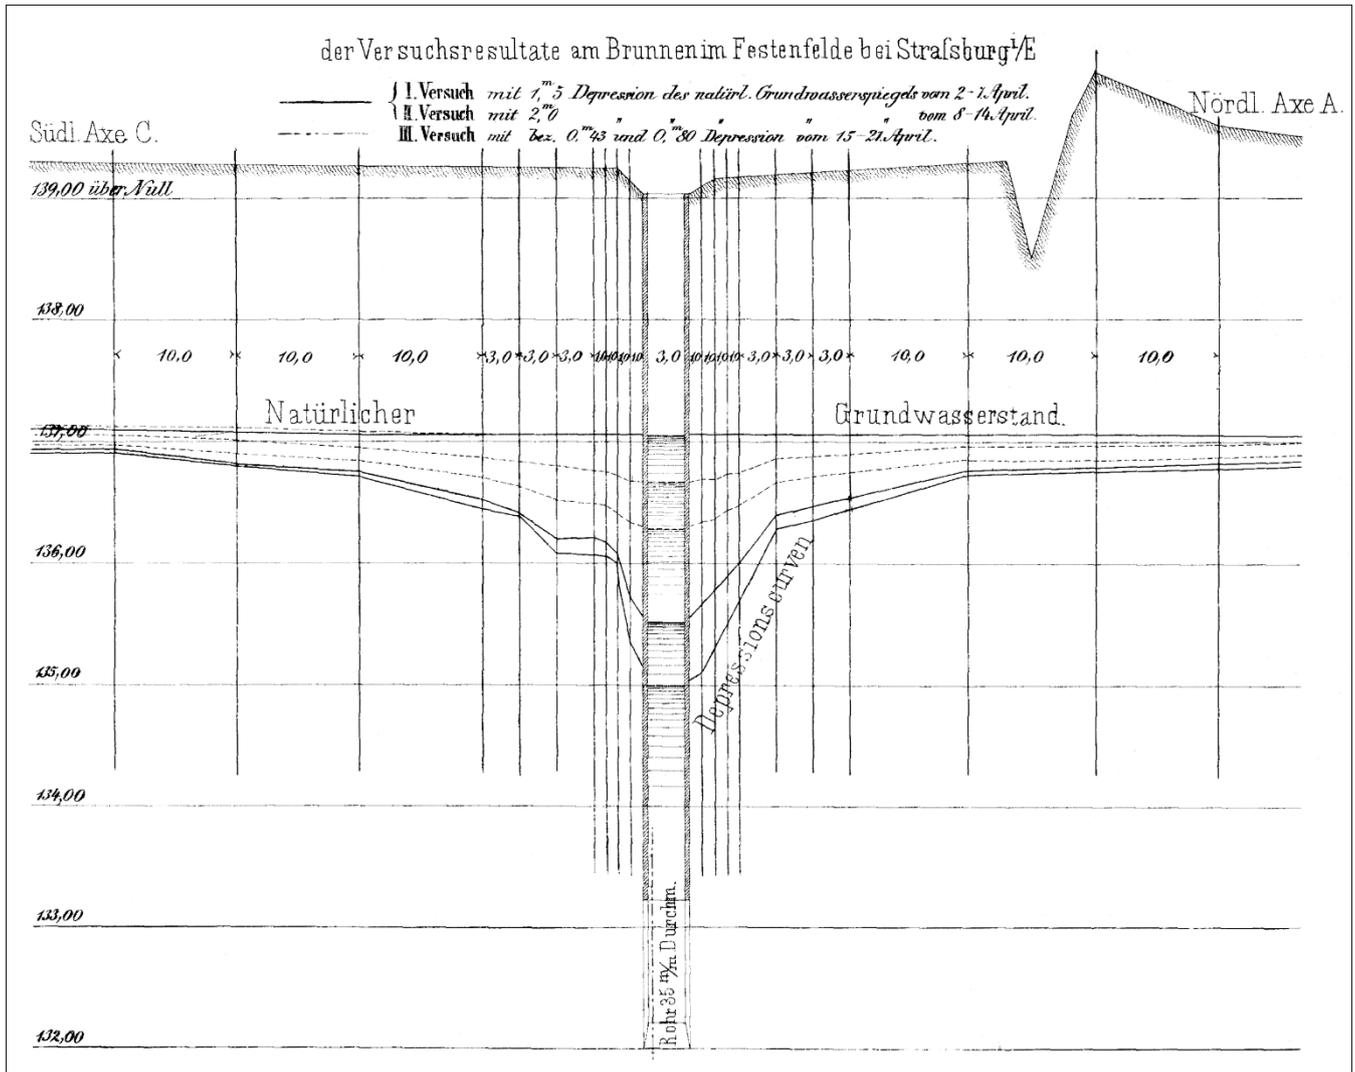

203

204 Although the first well-documented pumping test in Germany was performed in 1866 in Beesen near Halle/Saale by Bernhard  
205 Salbach (Houben, 2019), Adolf Thiem's work defined some of the standard procedures. Already for his first pumping tests in  
206 Augsburg, Strassburg/Alsace und Munich he developed several approaches that are still in use today (Thiem, 1876b, 1879a,  
207 1880). To delineate the geometry of the cone of depression and the radius of influence, he installed several observation wells,  
208 both perpendicular and parallel to the estimated flow direction of groundwater (Fig. 3). For this purpose, he mostly used  
209 Abyssinian wells ("Norton tubes"), sturdy prefabricated well tubes, usually of 50 mm inner diameter, which could be rammed  
210 into the ground and recovered – if necessary – afterwards. They were spaced more closely near to the well and further apart  
211 from it (Fig. 3). He also insisted on installing observation wells outside of the radius of influence to study the influence of  
212 natural variations of the groundwater levels, e.g., the ones caused by varying river water levels. By default, not only the  
213 drawdown phases for different pumping rates (Fig. 3) but also the recovery phase was observed (Thiem, 1876b). Another  
214 regular procedure was measuring the groundwater temperature during the test and taking water samples for later analysis.  
215 Already in Strassburg 1874/5 he used a "Locomobile mit Centrifugalpumpe", a submerged centrifugal pump driven by an  
216 external steam engine (Thiem, 1876b). The drive shaft of the pump was probably connected to the engine via a belt, like a  
217 primitive drive shaft pump.

218

219 Adolf Thiem used one procedure, which is not common anymore: he increased the depth of the pumping well during the test  
220 to find productive zones (Thiem, 1876b), as he had realized early on that thin layers of high conductivity provide a  
221 disproportional yield of water (van Lopik et al., 2020). He was also probably the first to notice – and quantify - the difference  
222 between horizontal and vertical hydraulic conductivity. From the results of his pumping test in Strassburg, he determined a  
223 value of eight for the ratio of horizontal to vertical conductivity (Thiem, 1876b). This is remarkably similar to the default value  
224 of ten recommended in most textbooks today. During his exploration of the hydrogeology around Leipzig, Thiem realized the

225 concept of multi-aquifer systems, i.e. the presence of several aquifers stacked on top of each other, separated by aquitards  
 226 (Thiem, 1881a). He referred to these individual aquifers as “Grundwasseretagen“ (groundwater floors/levels).  
 227

228  
 229 **Figure 3: Sketch of the cones of depression for different flow rates obtained during pumping tests in Festenfeld near**

 231 **(Thiem, 1876b). Translation: Natürlicher Grundwasserstand = natural groundwater level, Rohr = well diameter: 35**  
 232 **mm, Depressionskurven = pumping level curves, Versuch = Test, Versuchsergebnisse = test results, über Null = above**  
 233 **(French) sea level, Südl./Nördl. Axe = southern/northern axis.**

234

235 Dupuit (1863) had realized that flow in pipes connected to the well, e.g. a riser pipe, can cause additional head losses. To  
 236 address this, he brought back a velocity term from his studies on pipe flow and added it as a second term, very similar to the  
 237 one shown in Equation 3. Again, Thiem (1870) follows him in this, adding a velocity term in the slightly different form of the  
 238 well-known Darcy-Weisbach equation (Eq. 3). Interestingly, Dupuit (1863) references his previous work as the source for the  
 239 velocity term, and Thiem (1870) calls it a “well-known equation” without citing any reference. Both thus ignore the  
 240 contribution by Julius Weisbach (1845).

241

$$242 \quad h_2 - h_1 = \frac{Q}{2 \cdot \pi \cdot K_{aq} \cdot B} \cdot \ln\left(\frac{r_2}{r_1}\right) + f_D \cdot \frac{L_B}{4 \cdot r_b^5 \cdot \pi^2 \cdot g} \cdot Q^2 \quad (3)$$

243 with

244  $f_D$  = Darcy friction coefficient

245  $L_B$  = length of borehole (L)

246  $r_b$  = radius of casing/screen (L)

247  $g$  = acceleration of gravity (L/T<sup>2</sup>)

248

249 Dupuit (1863) realized that he could use the velocity term to investigate the relative influence of pipe flow on well hydraulics.  
 250 He retroactively studied two wells in Grenelle and Passy, both near Paris. Again, Thiem (1870, 1879) converted Dupuit’s  
 251 theoretical approach into a practical tool, the step-discharge test, which is still being used today. Therefore, he simplified  
 252 Equation 3 to

253

$$254 \quad H - h = K_{aq} \cdot Q + k_w \cdot Q^2 \quad (4)$$

255 with

256  $H$  = head in well at zero flow [L]

257  $h$  = head in well while pumping (steady state) [L]

258  $Q$  = pumping rate [L<sup>3</sup>/T]

259  $K_{aq}$  = hydraulic conductivity [L/T]

260  $k_w$  = well loss coefficient [T<sup>2</sup>/L<sup>5</sup>]

261

262 This equation is still the main model to interpret step-discharge tests today. In his pump tests, Thiem plotted the drawdown  $s$   
 263 as a function of different pumping rates  $Q$  and could identify the presence and quantify the contribution of the velocity term,  
 264 or in other words, the non-linear laminar and turbulent losses of the well itself (Houben, 2015a, b). If the  $s$ - $Q$  pairs plotted on  
 265 a straight line, the flow was laminar and the velocity term negligible. Any deviations from a straight line could then be

266 attributed to additional well losses and quantified. Therefore, Thiem usually employed several pumping rates during his tests,  
267 plotted the resulting drawdown curves and evaluated the contribution of non-laminar flow (e.g. Thiem, 1876a,b, 1879, 1880).  
268

269 Adolf Thiem realized that removing fines from the aquifer at high pumping rates can improve its hydraulic conductivity and  
270 thereby discovered the principle of well development (Thiem, 1875). In some cases, he took this to the limit and beyond. In  
271 the course of a pumping test in Strassburg/Alsace, the highest pumping rate of 136 l/s (490 m<sup>3</sup>/h) induced such a high degree  
272 of suffusion that the ground around the well subsided, and the well tubing was deformed (Thiem, 1875).  
273

274 The method for pumping test evaluation after Adolf Thiem (1870) remained one of the most important hydrogeological tools  
275 for several decades. It was intensively discussed and applied in the USA (Wenzel, 1932, 1933, 1936, 1942; Meinzer, 1934),  
276 which can be traced back to the good contacts of Günther Thiem to the leading USGS hydrogeologist of its times, Oscar  
277 Meinzer (see section 4). The Dupuit-Thiem method was not without flaws: as a steady state method, it commonly required  
278 long times until the drawdown had become stable and needed two observation wells. The transient method by Theis (1935),  
279 which does not require steady drawdown and can do with one observation well, was the first serious challenger but remained  
280 problematic due to the use of type curves, which was both tedious and a bit subjective. Only its later simplification by Cooper  
281 und Jacob (1947) relegated the Dupuit-Thiem method to the second place.  
282

283 Nevertheless, the Dupuit-Thiem equation can still be found in many textbooks (e.g. Batu, 1998; Kruseman and de Ridder,  
284 2000; Bear, 2007; Kresic, 2007; Kasenow, 2010). Due to its geometrical set-up and simple mathematics, it is often used to  
285 teach students how to derive analytical models for groundwater flow (e.g. Hendriks, 2010). It is still helpful for the design of  
286 water wells and the planning of construction dewatering (Houben 2015a,b). For pumping tests, it has become a niche method  
287 when steady-state pumping test data are available (Misstear, 2001). The Dupuit-Thiem equation forms the basis for several  
288 later analytical models, including the old but still commonly used Forchheimer (1901) model, which describes the contribution  
289 of non-linear flow processes in the flow towards wells (Houben, 2015a,b). The Forchheimer equation consists of two terms;  
290 the first is the Dupuit-Thiem equation, which describes the linear laminar losses. The second term describes the non-linear  
291 laminar losses. Until today, the Dupuit-Thiem equation is used as a base-case for validation or as quality control for more  
292 advanced analytical models (see Tügel et al., 2016 for examples). Despite its simplicity and biblical age of 150 years, to this  
293 day, the Dupuit-Thiem equation is still an important method for groundwater professionals worldwide.  
294

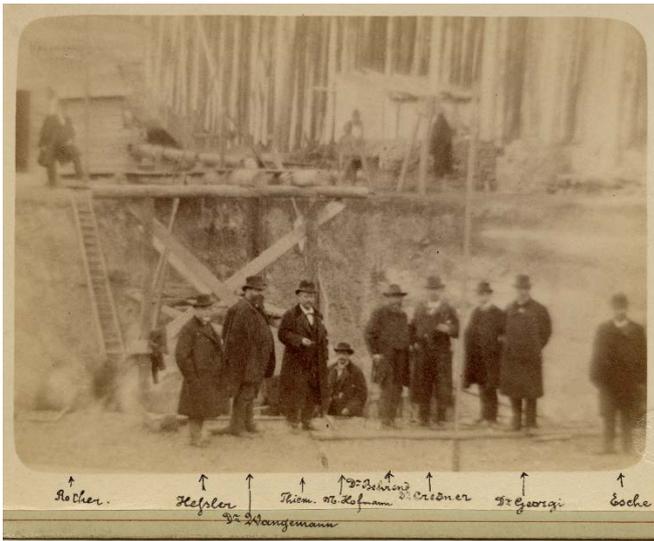

295 Prior to the full development of vertical wells, many hydrologists used backfilled drainage trenches instead, which could be of  
296 substantial length and depth (Houben, 2019). While working for the water supply of Winterthur, Switzerland, with Heinrich  
297 Gruner, Adolf Thiem considered such an option (Thiem, 1870). Therefore, he adapted his equation for well flow to a linear  
298 sink. Despite its simplicity, it only considered the height of the water table from the constant-head boundary to the drain in a  
299 2D projection (Thiem, 1870). This was probably the first model for horizontal wells.

### 300 **2.3 Contributions to well design**

301 The first pumping wells Thiem had used were shaft wells of large diameter, e.g. in Strassburg. They were difficult and  
302 expensive to build and often displayed poor performance. He realized that he could overcome these problems by developing  
303 the concept of the Norton wells (Abyssinian wells) further, which he had used as observation wells during his pump tests. In  
304 1881-83, for the water works of Naunhof (Leipzig), he increased their diameter to 150 mm, which still allowed them to be  
305 rammed into the subsurface. At first, he tried to emulate the shaft wells by installing so-called “Ringbrunnen” (ring wells), a  
306 central collector shaft surrounded by up to 20 individual rammed vertical wells, aligned on a circle with a radius of 10 m from  
307 the shaft (Engemann, 1989). The vertical wells were drilled first and then partially excavated down to the depth of the pipeline  
308 towards the central collector (Fig. 4). The latter still proved to be a difficult and expensive construction, and the many wells  
309 tended to interfere with each other. The Ringbrunnen were operated until 1926 (Engemann, 1989).

310

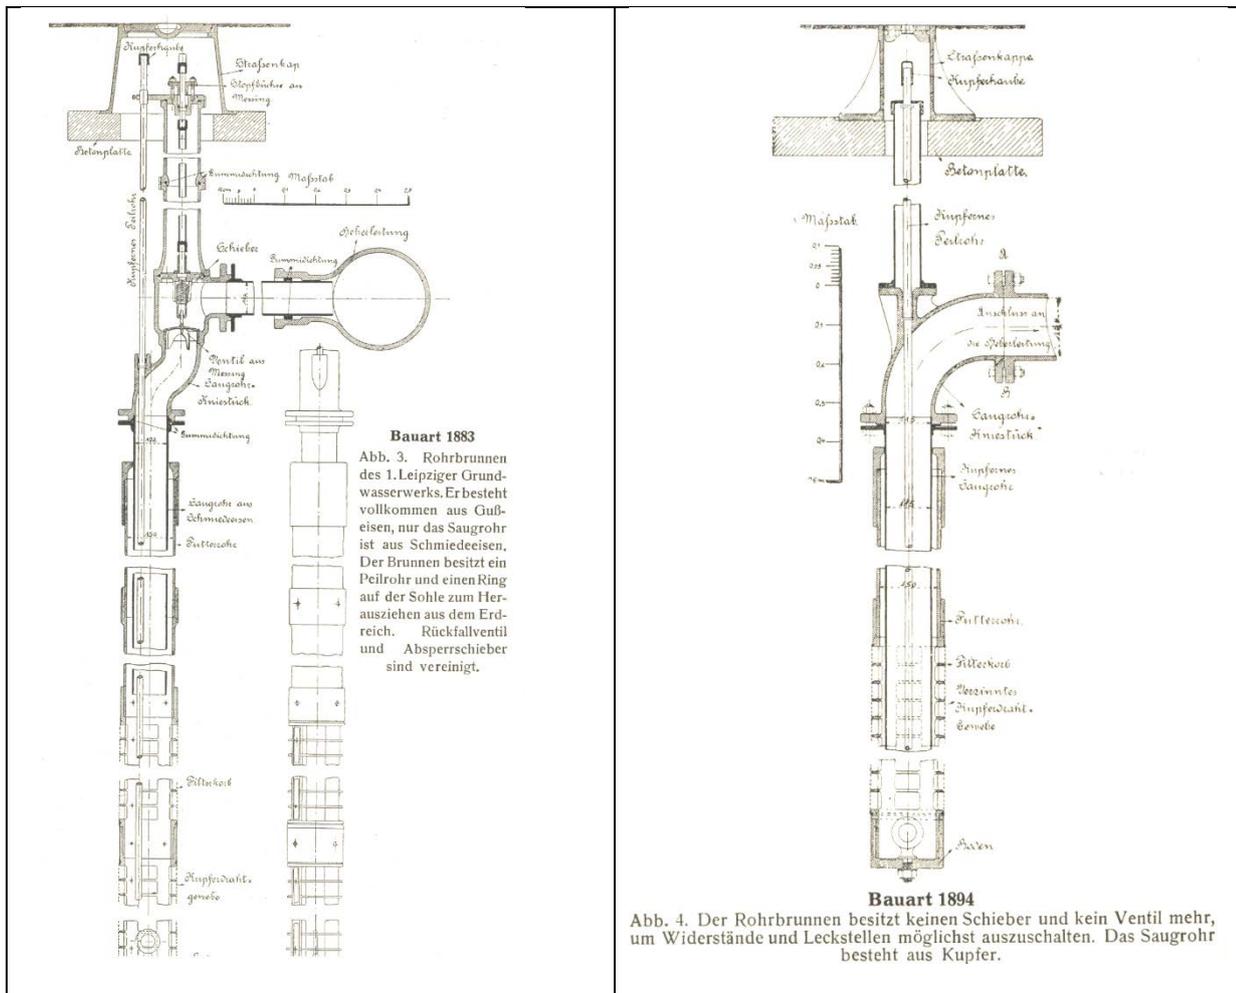

311 Later, he installed vertical well galleries, connected to a central siphon pipeline. This concept proved to be much more useful  
312 and cost-effective and became the standard. However, the vertical wells caused a lot of trouble due to corrosion, sand intake  
313 and incrustations, which often led to their complete failure to deliver water after only a few years. Thiem even equipped his  
314 wells with a noose, attached to the bottom, which could be used to pull out the whole well (Fig. 5). Later, a detachable screen  
315 was tried (Thiem, 1925). Thiem introduced cast iron as a material for screen and casing, which was more corrosion-resistant  
316 than the forged iron used before. Since the slots in the cast or forged iron screens were – due to technical reasons - quite wide  
317 (often up to 1 cm), sand control was a critical problem. Many wells filled with sand eroded from the aquifer quite quickly. The  
318 solution used by Thiem was to wrap fine metal meshes around the screens, which, however, were prone to blockage by the  
319 very fines they were supposed to retain and by corrosion and incrustations. Due to their small diameter and the described  
320 clogging processes, the yield of the early Thiem wells was quite small, often in the range of a few cubic meters per hour.  
321 Therefore, Thiem had to install 225 of them for the first well field of Leipzig in 1883 and 300 for a later one (1907) in the  
322 same town (Thiem, 1925). Thiem kept tinkering with the well design, e.g. by simplifying the design (Fig. 5), increasing the  
323 diameter to 150 mm (1907 in Leipzig), installing rubber seals and introducing copper pipes, which were lighter, easier to  
324 manufacture and much more corrosion-resistant, although more expensive. For the Nuremberg water works, the tedious and  
325 problematic metal meshes were replaced by an artificial gravel pack, a technique that had already been used for horizontal  
326 drains (Thiem, 1879; Houben, 2019). In Nuremberg, Thiem (1879) proposed a gravel pack of four layers with gradually  
327 increasing grain size towards the well (2, 4, 8, 15 mm). The well itself was made from perforated brickwork.

333

334 **Figure 5: Well designs by Adolf Thiem used in Leipzig. Left: first design from 1883, cast iron screen, riser pipe from wrought iron;**  
 335 **right: simplified design from 1894, backflow valve omitted, suction pipe now made of copper (Thiem, 1925).**

336

337 Thiem also found time to study the flow of groundwater towards wells under laboratory conditions. In 1879 and 1882, Gustav  
 338 Oesten had presented sandtank experiments on the groundwater flow to vertical, partially penetrating wells installed at two  
 339 different depths in a square box (Oesten, 1879a, 1882a,b,c). Using colour tracers, he correctly observed that the highest flow  
 340 velocities occurred around the screen. For a short screen installed at shallow depth, he found that coloured water from the  
 341 bottom of the aquifer did not flow to the well (Oesten, 1882a). He thus postulated an interface separating a pumping-affected  
 342 from a not affected area. Only a deeper placement of the screen induced flow from below. Adolf Thiem was very unhappy  
 343 with this and stated in his rebuttal that his previous theoretical work had already clarified how water should flow around a well  
 344 (Thiem, 1879d, 1882). However, he still felt obliged to perform his own sandtank experiments, which he called “*demonstratio*

345 *ad oculos*” (Latin for “demonstration to the eyes”). At first, he used a square box but later a wedge-shaped sand body to  
346 simulate the convergent flow towards the well. The main objection of Thiem on the experiment of Oesten (1882a) was that Mr  
347 Oesten infiltrated water through a small trench at the surface of the box. As this did not represent the reality of flow to wells,  
348 Thiem allowed water to be infiltrated from one side over the entire thickness of the sand and the water level in this reservoir  
349 was kept constant by an overflow (basically a constant head boundary). The well was simulated by a little sieve body from  
350 which water was extracted. The images indicate that the bottom of the well was probably not closed. The well screen only  
351 covered the uppermost third of the saturated aquifer thickness. The flow paths were visualized by injecting small volumes of  
352 coloured water at different depths at the inflow side. This conclusively showed that water from below the screened interval  
353 also entered the well, inducing a vertical flow component close to the well and elevated inflow rates at both the top and the  
354 bottom of the screen. Thus, Thiem had conclusively demonstrated the flow field around a partially penetrating well. Mr. Oesten  
355 responded to the rebuttal (Oesten, 1882b), claiming rather unconvincingly that Thiem had not sufficiently considered the  
356 influence of capillarity, but the case was settled.

357

358 Unbeknownst to many well designers, Adolf Thiem defined one of the most critical and most criticized values, the maximum  
359 permissible entrance velocity. Many textbooks and international standards on well design cite a value of 0.03 m/s (0.1 ft/s),  
360 e.g. Campbell and Lehr (1973), Driscoll (1986), Sterrett (2007). Keeping the entrance velocity below this value is said to curb  
361 head losses, maintain fully laminar flow conditions, prevent suffusion of sand particles, minimize incrustation build-up and  
362 even to control corrosion. The value is sometimes attributed to Bennison (1947), who, however, presented neither theoretical  
363 concepts nor experimental or field data to back up his claim. It is very likely that this value goes back to experiments executed  
364 by Adolph Thiem, while he was designing wells and their gravel packs for the Nuremberg waterworks (Thiem, 1879). Thiem  
365 understood that the flow velocity of groundwater is the critical parameter that controls particle mobilisation and thus sand  
366 intake. Therefore, he investigated the minimum vertical flow velocity required to keep grains of different diameters in  
367 suspension. At velocities below, the grains would not be transported. For sand grains up to a grain diameter of 0.25 mm he  
368 obtained maximum flow velocities under which no transport would take place of 0.028 m/s, which is basically the  
369 recommended value above. The value found its way into the influential German textbooks by Smreker (1914) and Thiem’s  
370 pupil Emil Prinz (1919) and the monograph by G. Thiem (1928). It is quite probable that US hydrologists became aware of  
371 this value from the German literature and through personal exchanges between Oscar Meinzer of the USGS and Günther Thiem  
372 (see below) and adopted it without further questioning.

373

374 For the water supply of the town of Greifswald, located at the German Baltic Coast, Adolf Thiem built a rather unusual  
375 construction in 1890 to extract groundwater. He had found an artesian aquifer of 6 m thickness under a confining layer of 5 m  
376 of glacial till (Houben, 2019). Instead of wells, he had a trench of 9 m depth and 450 m length constructed, equipped with two  
377 strings of perforated stoneware tubes of 500 mm diameter each, installed at different depths and then backfilled. He also had

378 an impervious underground cut-off wall installed to impound the groundwater, allowing it to flow towards the town by gravity  
379 alone. Unfortunately, this most likely very expensive construction never lived up to the expectations. The yield was very low  
380 at 10.8 m<sup>3</sup>/h and soon had to be augmented by additional vertical wells.

#### 381 **2.4 Development of tracer test methods**

382 Although reports on - sometimes involuntary - tracer experiments in karst aquifers predate the 19<sup>th</sup> century, Adolf Thiem  
383 played a crucial role in developing tracer experiments into a scientific instrument, especially for porous aquifers (Thiem, 1887,  
384 1888). His first field tests were done in 1886 in the towns of Greifswald and Stralsund, located at the Baltic Coast of Germany.  
385 He dissolved 75 to 100 kg of table salt (NaCl) in water and measured the breakthrough curves in several observation wells  
386 (Thiem, 1888). Therefore, the chloride concentrations were determined via titration with silver nitrate, using potassium  
387 chromate as an indicator. During a tracer test in Plauen (Saxony), he observed five to six tracer peaks, which he attributed to  
388 the heterogeneity of the aquifer. To understand the fundamental processes of tracer migration Thiem (1888) performed  
389 laboratory experiments using a sand column of 4 m length. Based on his experiences, Thiem (1888) was the first to postulate  
390 fundamental requirements for tracer chemicals: (1) non-reactive, (2) non-toxic, (3) cheap and (4) easy and quantitative analysis.

#### 391 **2.5 Equipotential and hydrogeological maps**

392 During his work in Augsburg with Gruner, Adolf Thiem made extensive use of Norton (or Abyssinian) wells, small but thick-  
393 walled pipe screens that could be rammed into the ground, to measure groundwater levels. Since they also determined the  
394 ground elevation of the observation wells, they were able to construct one of the world's earliest isopotential maps in 1873  
395 (Mommensen, 1962; Dassargues et al., 2021). Strangely enough, Thiem considered the map produced for a later project in  
396 Strassburg, Alsace (now Strasbourg, France) as his first isopotential map, probably because he published a detailed account of  
397 this study in the *Journal für Gasbeleuchtung und Wasserversorgung* (Thiem, 1876b), which was widely received and  
398 acclaimed. Figure 6 shows a typical example of Thiem's clear graphical style, showing equipotentials based on observation  
399 wells, time series of groundwater levels and cross-sections showing aquifer thickness and water table.

400

401 Thiem immediately realized the influence of the water level of the neighbouring river Rhine on groundwater levels and thus  
402 constructed two equipotential maps, one for high and one for low river stages (Thiem, 1878). Due to its importance, the original  
403 drawing of the equipotential map was donated to the German Museum (Deutsches Museum) in Munich (Thiem, 1929q, 1941a),  
404 the most important technical collection of Germany. Unfortunately, it seems to have been lost during the war, as a request for  
405 it with the museum archive in 2020 by the authors led to no results. However, a copy is reproduced in some publications of  
406 Günther Thiem (1929q, 1931f, 1941a).

407

417 contributions to a geological map (Thiem 1881c; Sauer 1881; Sauer et al., 1906). The cooperation with geologists was thus no  
418 anathema to Thiem. It had been the geologist Prof. Hermann Credner (Fig. 4), head of the Saxonian Geological Survey, who  
419 pointed Thiem towards Naunhof, where the second water works for Leipzig was installed in 1887, the largest and most modern  
420 groundwater works of Europe at the time (Credner 1883; Thiem 1892a,b; Heinker 2005). Credner later supported Günther  
421 Thiem when he wanted to become a member of the German Geological Society in 1911.

## 422 **2.6 Artificial groundwater recharge**

423 Thiem quickly realized that not all aquifers were productive enough to satisfy the demand and that an augmentation via surface  
424 water might be useful (Thiem, 1898). Early on, he studied bank filtration, e.g. in Fürth in 1880 and for the town of Essen, and  
425 recommended using temperature as a tracer to distinguish ground and surface water (Thiem, 1898). He was also aware of the  
426 danger of colmation of the riverbed (Thiem, 1929q). For the water supply of Stralsund, Thiem had unsuccessfully proposed  
427 artificial groundwater recharge via drainage trenches (Thiem, 1888b), a concept already applied in Chemnitz in 1875, using  
428 trenches with an artificial sand bed (see discussion in Thiem, 1898; Houben, 2019). However, Thiem's Swedish pupil Johann  
429 Gustaf Richert (1857-1934) perfected the concept (Svensson, 2013). It was implemented for the first time in Göteborg in 1898.  
430 Richert published his experiences in a book in German (Richert, 1911), and the concept became quite popular in Germany  
431 after the turn of the century, especially in the Ruhr valley.

## 432 **2.7 Construction dewatering**

433 The construction of deep basements often requires working in the saturated zone and thus the control of groundwater. In the  
434 19<sup>th</sup> century, this problem was – if not avoided altogether – tackled by encapsulating the construction site and sealing it off  
435 from the surrounding groundwater, e.g. by ramming sheet piles, injecting cement or freezing parts of the aquifer. These  
436 procedures were technically demanding, costly and not always successful. Adolf Thiem realized that dewatering by verticals  
437 wells was a viable alternative since the well type he had developed could be installed cheaply and quickly, and his equations  
438 allowed him to dimension the dewatering scheme. In 1886, Thiem applied this concept, using a shaft well, for the first time in  
439 the construction of the Leipzig water supply in Naunhof (Prinz, 1907; Thiem, 1929q, 1931f). Therefore, Thiem can be  
440 considered one of the founding fathers of construction dewatering.

## 441 **2.7 Scientific feuds**

442 Thiem regularly attended conferences, e.g. those of the German Association of Water Professionals (DVGW), and was an avid  
443 contributor to the discussions (e.g. Thiem 1880b,c,d, 1885c, 188b,c). He did not shy away from voicing controversial opinions,  
444 which led to some prolonged scientific feuds.

445

446 The main opponent of Adolf Thiem was Oskar Smreker, born in 1854 on Castle Görzhof/Cilli, Austria-Hungary (now Celje,  
447 Slovenia), and died in Paris in 1935. He was a graduate of the Swiss Technical University (ETH) Zurich (1870-1874), where

448 he, much later, in 1914, at the age of 60, received his PhD on a groundwater-related study (Smreker, 1914a). In 1876, he was  
449 hired by Heinrich Gruner in Regensburg as a replacement for A. Thiem, after Gruner and Thiem had parted ways, but he was  
450 sacked in 1877 (Mommsen, 1962). After several years as an engineer in Germany and Italy, Smreker founded a successful  
451 company in Mannheim, Germany, in 1882 that designed and built many groundwater supply systems in Germany and abroad.  
452 Smreker published several papers (Smreker, 1878, 1879, 1881, 1883, 1907), criticising both the work of Darcy (1856) and  
453 Thiem (1870, 1876b). He doubted the validity of the Darcy law - and the Dupuit-Thiem equation deducted from it - due to the  
454 supposed ignorance of the increase of velocity around a well. He even formulated his own non-linear law of groundwater  
455 movement and dared to use the results of Thiem's pumping tests from Strassburg to test it (Smreker, 1878). Adolf Thiem  
456 responded by citing ample literature based on both field and experimental data, which showed the validity of Darcy's law for  
457 practically all applications (Thiem, 1880).

458

459 Even after Thiem had died in 1908, Smreker would not relent. In his 1914 PhD thesis, several papers, and his textbook, Smreker  
460 still attacks the validity of Darcy's law and upholds his alternative law (Smreker, 1914a,b, 1915a,b,c,d,e). He argued that "*The*  
461 *Darcy law [...] fails completely when applied to the principle of groundwater abstraction, because the differences in velocities*  
462 *at the varying distances from the well are large*" (Smreker, 1914). Several prominent authors, including Max Rother (1855-  
463 1928), Adolf Thiem's last collaborator, felt obliged to publish a defence of the Darcy law. In the middle of the First World  
464 War (WW1) and shortly afterwards, a war of papers ensued across several journals and countries and arguments flew back  
465 (Brix, 1915; Rother, 1915, 1916a,b, 1919a,b, 1920; Lummert, 1916a,b, 1917a,b; Hocheder 1919) and forth (Smreker,  
466 1915a,b,c,d,e,f, 1916a,b, 1918, 1919, 1920a,b,c), with Smreker receiving support from Hache (1919) and Henneberg (1919).  
467 Based on an extensive experimental comparison of equations using a Darcy permeameter, which he calls "Thiem apparatus",  
468 Krüger (1918) found the best fit using a modified Smreker equation. Other authors, like Weyrauch (1916), the Dutchman J.  
469 Versluys (1915, 1919), the Austrian-Hungarian J. Zavadil (1915) and Zunker (1920), tried to reconcile the approaches by  
470 investigating their limits. The latter also proposed a new equation based on experimental data. In 1919, the Journal für  
471 Gasbeleuchtung und Wasserversorgung apparently had enough of the discussion and tried to declare it finished (Anonymous  
472 1919), to no avail (Rother 1920; Smreker 1920a,b,c). Adolf's successor, his son Günther Thiem participated only marginally  
473 in the feud (Thiem 1920i,l). He probably did not want to compromise his role as neutral editor of his journal (3.5). The feud  
474 lost steam in the early 1920s, after more than 40 years of struggle. Although several review papers had tried to declare  
475 Smreker's approach to be the correct one (Krüger 1918; Hache 1919), his struggle was in vain, and his equation fell into  
476 oblivion and is hardly cited today (Benedikt et al., 2018). Unbeknownst to most participants of the feud, Philipp Forchheimer,  
477 who was only marginally involved in it (Lummert 1916b), had already solved the problem in 1901 by proposing the law today  
478 known as Forchheimer law (Forchheimer 1901). It expands the Darcy law with a velocity term that can be used when flow  
479 velocities are high, e.g. in the vicinity of pumping wells. This fixes the deficiency of the Darcy law that Smreker had correctly  
480 identified. With low velocities, the Forchheimer equation reduces to the Darcy law, which thus remains valid for most  
481 situations. Smreker's feud with the Thiem School must have been quite bitter, as Smreker does not mention any hydraulic

482 study of neither Adolf nor Günther Thiem in his otherwise excellent book (Smreker, 1914). This is quite unusual for a time  
483 when there were few published studies available, and Thiem had already been recognized as the founding father of  
484 hydrogeology in Germany.

485

486 Another hydrologist who got into trouble with Adolf Thiem was Gustav Oesten, a civil engineer and sub-director of the Berlin  
487 water works, later the author of an influential textbook on water supply that went through several editions (Oesten, 1904). He  
488 had published on the flow of groundwater to well screens based on sandtank experiments and interpreted them in a non-Darcian  
489 manner (Oesten, 1879a), which Thiem attacked in a quite sarcastic style (Thiem, 1879c; Oesten, 1879b). In 1882, Oesten  
490 published basically the same results in a different journal (Oesten, 1882a). Again, Thiem attacked his interpretations and even  
491 conducted experiments to show his point (Thiem, 1882; Oesten, 1882b). Details can be found in section 2.3.

## 492 **3 Günther Thiem**

### 493 **3.1 Biography**

494 Günther Thiem was born under the full name Ernst Gerhard Günther Thiem on October 11, 1875, in Regensburg, Bavaria,  
495 where his father was working with Heinrich Gruner (1833-1906) at that time (Fig. 7). After his father had relocated to Leipzig  
496 in 1886, he attended the renowned Thomasschule, Germany's oldest public school, founded in 1212, which was right next  
497 door to his childhood home in the Hillerstraße. He started his academic career in 1895, studying philosophy at the University  
498 of Leipzig. In 1896 he changed to civil engineering at the Königlich Technische Hochschule (Royal Technical University) in  
499 Stuttgart to follow the classes of Robert Weyrauch (1874-1924) and Otto Lueger (1843-1911), the last being Germany's  
500 leading expert on water supply and author of influential textbooks (Lueger, 1883, 1895). During the semester breaks, Günther  
501 worked in his father's consulting company. Lueger in his book "The water supply of towns" (Lueger, 1895), advocated for the  
502 use of springs and groundwater instead of surface water (Loehnert, 2013). However, some of his theoretical concepts were  
503 wrong; he followed the doctrine that groundwater under free water table conditions could not flow upwards (de Vries, 2006).  
504 In 1901 he reappeared in Leipzig with the title "Regierungs-Bauführer" (government building headman), which indicates that  
505 he intended to join the saxonian state administration. But this was not meant to be. Instead, he pursued his PhD in Stuttgart  
506 (section 3.2) and later took over the family consulting company after the rather sudden deaths of his older brother in 1907 and  
507 his father in 1908 (section 3.4).

508

509 He married Erna Carola Auguste Goelitz (1887-1976) in Marburg in 1909. They had three children, all born in Leipzig:  
510 Auguste Luisa Ingeborg (born 1911), Anna Else Erika (born 1913), and Karl Wolf Gunther (1917-2015), the latter a renowned  
511 art historian and head of the graphical collection of the state art gallery in Stuttgart (Hoffmann, 2017; Herfried Apel, pers.  
512 comm). After the death of Adolf Thiem, Günther's family moved into the old Thiem residence at Hillerstraße 9, where they  
513 stayed at least until 1949 (entry in the last available address book) but probably even longer until Günther's death and possibly

514 beyond. Adolf's widow Thekla moved to the neighbouring Schwägrichenstraße, where she lived until her death in 1931. In  
515 the address book, she appears with the description "Privata", indicating a rich widow who could live from her inherited means.

G. Thiem.

517

### 518 **3.2 Thiem (1906) PhD thesis**

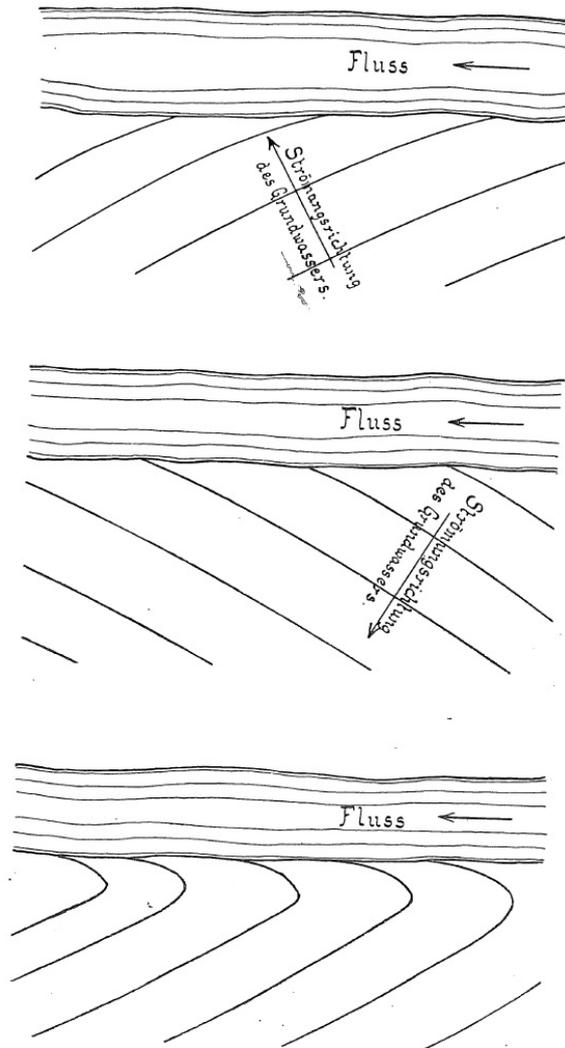

519 Otto Lueger was also the advisor of Thiem's PhD thesis, which Günther dedicated to his father (Thiem, 1906). It was probably  
520 one of the first PhD studies solely dedicated to groundwater and was widely received in Germany and abroad. The PhD was  
521 remarkably short; 45 pages with 3 annexes, providing 10 borehole descriptions, 3 tables with results of calculations and 8 plans  
522 or cross-sections. The thesis had no formal reference list but referred in the text to publications of six authors (Darcy, A. Thiem,  
523 Slichter, Forchheimer, Dupuit, Lueger). Verbatim quotes were referenced from Slichter and Dupuit in respectively English  
524 and French. In the thesis, he presented the so-called  $\epsilon$ -Verfahren (epsilon method). In essence, it was the Dupuit-Thiem  
525 pump test analysis method for obtaining the hydraulic conductivity. However, instead of using a hydraulic conductivity  $K$ , he  
526 defined  $\epsilon$ , which he called the unit capacity, as the product of the  $K$  and a unit cross-section normal to the groundwater flow.  
527 He derived and presented for unconfined and confined flow to wells, equations for  $\epsilon$ , i.e., the Dupuit-Thiem equations. He then  
528 applied this method by performing ten pump tests to estimate the groundwater flow in a 6 km long section of the Iser River  
529 valley (now Jizera River) near its confluence with the Elbe River, close to the city of Altbunzlau (now Stará Boleslav, Czech  
530 Republic). The pumping tests were part of a study to develop groundwater resources for Prague, a project initiated by Adolf  
531 Thiem (Anonymous, 1903). The field investigation was executed in the first half of 1902. He showed that the Iser River is the

532 receptor of the groundwater flow and that the higher the river bed is above the base of the unconfined aquifer and the closer  
533 one is to the river, the more vertical upward flow there is, which was in contradiction to the ideas of his advisor Lueger (1895).  
534

535 The last chapter of Thiem's thesis is probably one of the first published extensive analyses of groundwater-surface water  
536 interaction. Thiem explained and presented in clear figures how equipotential lines are differently oriented towards a river  
537 dependent on gaining or losing river conditions (Fig. 8). But also he showed how during an infiltrating flood wave passing  
538 through the river the equipotential lines change of curvature near the river. Hence, he recognized and described the process of  
539 bank infiltration and storage. During 5 months, in support of studying groundwater-surface water interaction, he observed  
540 groundwater levels in piezometers at different distances from the river at the ten pump test locations. In one of the ten locations,  
541 he suffered data loss due to vandalism of his piezometer, apparently an issue of all times. By calculating the changing gradients,  
542 he observed, e.g. on March 25, 1902, that the high river water levels caused infiltrating conditions in the valley aquifer. Based  
543 on observed strongly changing gradients in the time frame of 48 hours, he concluded that groundwater level observations  
544 during at least one year are required to obtain an average gradient with which the groundwater flow to the river can be  
545 estimated. He also extensively discussed the temporal changes in groundwater-surface water interaction and sources of  
546 extracted water under the influence of seasonal groundwater level variations and the regime of a near-river located well. In  
547 designing the well field, Thiem aimed to avoid extracting low-quality surface water. Hence, Thiem developed an analytical  
548 equation to estimate the required distance between the river and the well, based on phreatic flow between two assumed fully  
549 penetrating canals (representing the river and the well). In the same chapter, he discussed the different infiltration and recharge  
550 characteristics of the study area; low on the loamy valley soils and high on the sandy terraces. Moreover, he described the  
551 strongly delayed response of rainfall on the groundwater levels, warning that the delay is generally well underestimated.  
552

553 The proposed  $\varepsilon$ -Verfahren never became widely popular under this name, despite being discussed in detail in the book by Prinz  
554 (1919) in German but also in French by Imbeaux (1921, 1930). The approach Günther Thiem proposed was actually not novel  
555 as his father essentially already published in 1870 the derivation of the Dupuit-Thiem equation for estimating the hydraulic  
556 conductivity. Nevertheless, the 1906 PhD thesis very clearly details and applies the method and is well cited, at least 521 times  
557 (Google Scholar, Oct 2020). Often the thesis is erroneously cited as the source of the Dupuit-Thiem model or Thiem equation  
558 (e.g. Wenzel, 1936; Meinzer and Wenzel, 1940), but this honour belongs to Adolf Thiem (1870), which has so far received  
559 only 30 citations. The clear exposition of the Dupuit-Thiem equation and Günther Thiem's support in transferring his method  
560 to the US (see below) explain the erroneous citation.

566

### 567 3.3 Work overseas

568 After graduating in 1900, Günther Thiem went to the US and worked in New York for the Hering & Fuller consulting company.  
 569 One of the founders was the famous civil engineer Rudolph Hering (1847-1923), member of the “Hall of Fame“ of the  
 570 American Water Works Association and eponym of the “Rudolph Hering Medal“, awarded by the American Society of Civil  
 571 Engineers for outstanding contributions to environmental engineering. Being of German descent, Hering had been sent by his  
 572 parents to Dresden to attend school and university. Whether he came into contact with Adolf Thiem during this period remains

573 unclear. One of Günther Thiem's projects in the US was building the water supply for the city of Jersey, New Jersey. He also  
574 travelled to Egypt, India and Ceylon (Sri Lanka) during this time (Thiem 1915c, 1936c, 1955a). In 1903, he returned to Leipzig  
575 and became a junior partner in his father's company. While the bulk of the work there was in Germany, he was also involved  
576 in projects in Austria-Hungary, Switzerland and Russia (details see below).

### 577 **3.4 Consulting Engineer**

578 After the death of his older brother and father, Günther took over the consulting company in Leipzig in 1908, employing five  
579 to seven engineers and several technical staff (Anonymous 1910). In 1911, he moved the offices to Marschnerstraße 13, in  
580 1915 to Plagwitzer Straße 9 and finally in 1939 to Plagwitzer Straße 7 (today Käthe-Kollwitz-Straße), which was basically in  
581 the same corner house as his home in Hillerstraße 9. All mentioned buildings survived the war with minor damage, were nicely  
582 refurbished after the reunification and still exist today (Fig. 9). Public water supply companies were his main clients. For them,  
583 he designed and supervised the construction of many water supply schemes in Germany and abroad (Table 2). Most of them  
584 were based on groundwater and a few on bank filtration, which he considered artificial groundwater (Thiem 1919k). He also  
585 served in the city council of Leipzig (1913-1918 and 1921-1922). In 1912 he was appointed as "Gerichtlicher  
586 Sachverständiger" (surveyor appointed by the court). During the First World War, he served in the German Army as field  
587 engineer and published papers on military aspects, e.g. the construction and drainage of trenches (Thiem, 1915a, 1916e, 1917e),  
588 field water supply (Thiem, 1917a, 1919c) and the disinfection of water (Thiem, 1916d, 1918a, 1918d, 1919c). For his efforts,  
589 he was awarded the Saxonian medal of war merit (Kriegsverdienstkreuz), a fact that is curiously never mentioned in any of  
590 his later biographies (Anonymous 1917).

591

592 After the war, he applied his skills in the growing field of lignite mining, which had major impacts on groundwater resources  
593 through the dewatering of the open-pit mines in central Germany and Bavaria (Thiem, 1920b,m, 1921c, 1922a,b, 1923d,  
594 1924a,b, 1928e, 1929b,i, 1930b, 1935b, 1937d, 1938a, 1939e, 1940e, 1952). In his publications of this time, he introduced  
595 himself as "Montanhydrologe" (mining hydrologist) and tried to convince the mining engineers that geohydrology was an  
596 important contribution to their field. The industrial water supply also became important (Thiem, 1919k, 1920k, 1922e,  
597 1924c,d,e,f 1929l, 1931e, 1935d,e, 1937a). Building on the work of his father, he was also an important contributor to the  
598 improvement of the design and construction of vertical wells (Thiem, 1911d, 1916b, 1917d, 1919f, 1920c,d,j, 1923c,f, 1924h,  
599 1925a, 1928a,d, 1929f, 1936a, 1938d, 1941b, 1942, 1951b,c, 1953c,d). Similar to his father, he investigated hydraulic and  
600 economic aspects of pipeline networks (Thiem, 1910b, 1910h, 1912b,c, 1915d, 1918c, 1919b,d,e, 1920a, 1924c,e, 1931b,i,n,  
601 1932a,d,e, 1938b, 1954) and their maintenance (Thiem, 1914b, 1929d). Water treatment, especially the removal of ferrous  
602 iron, was a side issue (Thiem, 1910i, 1914d, 1915b, 1924d, 1928c,f, 1929a, 1931m). He also designed and, unlike his father,  
603 patented technical equipment, amongst them a device to measure groundwater levels (Thiem, 1908), a detachable riser pipe  
604 (Thiem 1911d), a water meter (Thiem 1911e,f 1912a), a device for screened wells allowing the injection of chemical reactants  
605 to dissolve incrustations (Thiem, 1931d), an acid-proof coating for metal well screens (Thiem 1931j), a rubber pipe seal (Thiem

606 1933d), a check valve with the wonderfully German name “Rückschlagklappenventil” (Thiem, 1935b) and a gate valve  
 607 (Thiem, 1937c).

608

609 **Figure 9: (left) Corner house Hillerstraße 9 (left) and Plagwitzer Straße 7 (right, today named Käthe-Kollwitz-Straße), Günther had**  
 610 **his offices in Plagwitzer Straße 9 (yellow building to the right) since 1915 and finally in Plagwitzer Straße 7 since 1939, (right)**  
 611 **Hillerstraße 9, the Thiem family residence: Adolf and his family lived there on the second floor since 1887, Günther took over in**  
 612 **1909 (Photos: Houben).**

613

614 Due to his age, he did not serve in the Second World War (WW2) but contributed several short publications detailing the water  
 615 supply for troops in the field, copying his work produced during WWI (Thiem, 1937b, 1940b).

616

617 **Table 2: Main water supplies planned and built by Günther Thiem (English names in parentheses)**

Name of city	Name of city today	Comment	References
Prag (Prague), Altbnzlau, Czech Republic	Praha, Stará Boleslav	then Austria-Hungary	Thiem (1906)
Landeshut	Kamienna Góra, Poland	then Germany	Thiem (1909b)
Harburg		today part of Hamburg	Thiem (1910a)
Wilhelmsburg		today part of Hamburg	Thiem (1910c)
Leipzig		expansion of previous schemes	Thiem (1910d,j, 1911a,b, 1912b, 1914c,

St. Moritz, Switzerland			Thiem (1933b,c, 1934b,c)

Samaden, CH			Thiem (1936b,d)
Dessau			Thiem (1955b)

618

619 Other cities he worked for include Zwickau, Freiberg, Spremberg, Gera, Linz (Austria), and Suceava, Romania, then Austria-  
620 Hungary (Pöpel 1956). In his study for Mönchengladbach, he lists the prices for several of his hydrogeological investigations,  
621 including drilling costs and their duration (Thiem 1911c). The investigations in Prague and Leipzig took about 200 days each  
622 and cost 51,000 and 30,000 German Mark. The study in Czernowitz took 67 days, while the one for Mönchengladbach required  
623 150 days, both at the cost of about 15,000 Mark. To roughly convert these prices into Euro, one has to multiply them by 5.2.  
624 During his work in Switzerland in the early 1930s, he briefly became technical director of the Hydrotechnik AG, Zurich (Thiem  
625 1933c).

### 626 3.5 Editor, publisher and author

627 In 1914, Günther Thiem became the executive editor of the „Internationale Zeitschrift für Wasser-Versorgung“ (International  
628 Journal for Water Supply), founded by the „Internationaler Verband der Wassersachverständigen“ (International Association  
629 of Water Experts) (Weber, 2020), the first international journal exclusively dedicated to hydrology. The journal was published  
630 through his own publishing company “Technischer Verlag Dr.-Ing. Günther Thiem”. Rudolph Hering (USA), Édouard  
631 Imbeaux (France), Felice Poggi (Italy) and J.G. Richert (Sweden) acted as additional editors (Fig. 10). His contacts thus went  
632 further than the US (see Section 4) and, despite all political problems, included the French-speaking world, e.g. through Prof.  
633 Imbeaux, whom he calls “..a dear old friend” in the letter shown in Figure 11. Even in 1916, when the war between Germany  
634 and France was in its third year, Günther Thiem published a paper on the water supply for Nice, France (Thiem, 1916a). The  
635 friendship with Imbeaux outlasted the war, and as early as 1921, Imbeaux promoted the Thiem epsilon method in an article  
636 (Imbeaux, 1921). Contributions to the journal came from all over the world, including from leading US hydrologists of the  
637 time, such as Charles Slichter (Slichter, 1915). Günther also republished several of his father’s older publications (A. Thiem,  
638 1914, 1915, 1918, 1920).

639

640 Interestingly, the 1917 issue of the journal still mentions all original foreign editors, although Germany was at war with France  
641 and Italy (Hoefer von Heimhalt from Vienna and his former teacher Robert Weyrauch from Stuttgart had been added  
642 meanwhile). The journal was active throughout WW1, but only published articles in German. In 1918, Günther Thiem realized  
643 that the term “International” in both the journal title and the name of the association was awkward at a time of war and dropped  
644 it. The names of Hering, Imbeaux and Poggi disappeared as coeditors, while H. Peter from Zurich, Switzerland, was added. In  
645 mid-1919, the journal was renamed “Zeitschrift für Wasserversorgung und Abwasserkunde” (Journal for Water Supply and  
646 Wastewater Science). In 1920, he decided to give up the journal, and it was subsequently merged into the journal “Wasser und  
647 Gas”, which appeared until 1934, with Günther serving as associated editor. He also worked in the same position for the

648 “Kalender für das Gas- und Wasserfach”, a yearbook for the gas and water field, which appeared between 1921 and 1938.  
 649 After WW2, Günther Thiem did reappear as editor of a journal: from 1951 to 1956 he was listed as co-worker of the journal  
 650 “Bohrtechnik, Brunnenbau (Drilling technique, well construction)”. Ironically, after his death in 1959, the East German  
 651 government forgot to delete his now inactive publishing company from the public registry. Finally, in 2007, several years after  
 652 the German reunification did the authorities finally delete it.  
 653

654  
 655 **Figure 10: Header of the “Internationale Zeitschrift für Wasser-Versorgung” (1917), showing the international co-editors and the**  
 656 **journal title in different languages.**

657  
 658 Günther Thiem was a prolific author. He left a legacy of around 200 publications treating theoretical concepts, technical  
 659 inventions, case studies from his consulting work and promoting the general benefit of groundwater. He repeatedly published  
 660 papers or booklets that summarized the gained knowledge on hydrogeology (e.g. Thiem, 1907, 1909a, 1913d, 1914a, 1917b,c,  
 661 1918b,e, 1919g, 1920e,h, 1922d, 1923e, 1925b,c, 1926a, 1927a,b, 1928b, 1929j,l, 1930a,c, 1931a,f,g,k, 1939f, 1940d,f, 1941a,  
 662 1951a, 1953a,b, 1955c; Thiem and Gagneur, 1929). His interest in international hydrological affairs is evidenced by several  
 663 review articles on foreign water supply schemes, stretching as far as the Soviet Union and Egypt (Thiem 1915c, 1916a, 1923b,  
 664 1924g, 1936c). Many of his publications appear in a series published by himself, called “Thiems Hydrologische Sammlung”  
 665 (Thiem’s Hydrological collection), a series of small booklets, which often are reprints of some of his papers published in  
 666 Journals. He was also a great communicator whose oral explanations of by integrals supported hydrological calculations, were  
 667 even understandable for lawyers (Grahmann, 1960). This was often necessary since the quantitative methods introduced by  
 668 both Thiems were initially often met with scepticism. As late as the early 20<sup>th</sup> century, a senior government official told Günther

669 Thiem “*Your whole hydrology is nonsense, I simply build well after well, until I obtain the desired quantity of water*” (Thiem  
670 1911c). Luckily, these random searches for groundwater, often “aided” by the use of the divining rod, were slowly overcome  
671 due to the persistent work and the publications by both Thiems. During his search for groundwater for the city of Bautzen,  
672 Günther actually hired two water diviners to compare their results to his drill holes, with less than convincing results for the  
673 divining rods (Thiem 193b,h,l).

### 674 **3.6 Honours**

675 Like his father’s work, Günther’s contributions to Leipzig and Prague's water supply were considered important enough to be  
676 shown at the world exhibition in Brussels 1910, where he was even awarded a silver medal (Stoffers, 1910). The occasions of  
677 his 60<sup>th</sup>, 75<sup>th</sup> and 80<sup>th</sup> birthdays in 1935 and 1955 were honoured by the publication of short biographies (Anonymous, 1935,  
678 1950, 1955, 1956; Lang 1950; Paavel 1955; Herzner 1955). Although not of working class background, Thiem was also  
679 honoured by the East German communists, who took over in Leipzig after WW2. In December 1952, they awarded him the  
680 somewhat peculiar title “*Verdienter Techniker des Volkes*” (merited technician of the people), one of the first to receive this  
681 honour (Henneberg, 1952). In the same year, he was appointed Ehrensenator (honorary senator) of the Hochschule für  
682 Bauwesen (University of Construction) in Leipzig (Schöne, 1959). Not to be outdone, he also received prizes from West  
683 Germany. In 1956, the German Association for Gas and Water (DVGW) awarded him their highest honorary prize, the Bunsen-  
684 Pettenkofer-Ehrentafel (Ehrentafel = shield of honour, Anonymous 1956), and the Technical University of Stuttgart  
685 commemorated the 50<sup>th</sup> anniversary of his PhD by awarding him the Golden PhD diploma (Pöpel 1956; Schöne, 1956). His  
686 death was mourned in both East and West Germany (Anonymous 1959a; Anonymous 1959b; Schöne 1959; Grahmann 1960).

### 687 **4 Günther Thiem and Oscar Edward Meinzer**

688 The work by Adolf Thiem had already been noted in US literature (e.g. King and Slichter, 1899), but it was Günther who  
689 popularized the Thiem methods abroad, especially in the US. Trying to understand the background to why generally in the US  
690 literature (Ritzi and Bobeck, 2008) the Dupuit-Thiem equation is called the Thiem method after Thiem (1906), and why it  
691 became so popular, we investigated the contacts between Günther Thiem and US scientists, especially Oscar Edward Meinzer.  
692

693 C.V. Theis, former District Geologist and Division Scientist at the USGS Division of Ground Water from 1930 till his official  
694 ‘retirement’ in 1970, was interviewed by John Bredehoeft in 1985 (Theis, 1985; Bredehoeft, 2008). “CV” was at that time  
695 already 85 years old. Although he took time to respond, his mind was still sharp, and he remembered quite clearly (Bredehoeft,  
696 2008). Bredehoeft asked CV about the pumping test in Grand Island, Nebraska, run by the USGS (Wenzel, 1932, 1933, 1936).  
697 Theis replied that Meinzer had gone to Europe to meet Günther Thiem, who had been using pumping tests for water supply,  
698 and “*brought back the idea and to really try it out*”. He said “*it was the only one at that time [in this country], ..., well, no,*  
699 *who was it that presumably made some sort of a pumping test in Pennsylvania?*”. He also related that “*this was just before*

700 *Hitler's time and Meinzer was sending back to Thiem various baskets of food because Thiem was having a hard time there".*  
701 The food baskets were most likely sent after the war since Thiem was a successful businessman before it.  
702  
703 The Grand Island pumping test was planned in 1930 under the supervision of O.E. Meinzer, who was since 1912 Geologist in  
704 charge of the Division of Ground Water of the USGS. The measurements took place in summer 1931; results were described  
705 in short in Wenzel (1932, 1933) and fully documented in Wenzel (1936). The goal of the two performed pumping tests was  
706 *"to ascertain the accuracy of the Thiem method and to investigate the possibilities of determining specific yield by a pumping*  
707 *test"* (Wenzel, 1936). The Wenzel 1932 and 1936 publications both have in their title "The Thiem method for determining  
708 permeability of water-bearing materials..." and described the method extensively. Meinzer (1932) also explained the method,  
709 it is likely that he presented the method already at a meeting of the Society of Economic Geologists in New York City, Dec.  
710 29, 1928: *"Mimeographed copies of the paper in abbreviated form had been sent to the members prior to the meeting. The*  
711 *paper has been revised and enlarged for the present publication"* (Meinzer, 1932). Both Meinzer and Wenzel referred to A.  
712 Thiem, particularly the Thiem (1887) tracer test paper but not to the Thiem (1870) paper. However, Meinzer (1934) referenced  
713 also Adolf Thiem (1870): *"He introduced field methods for making tests of the flow of ground water and applied the laws of*  
714 *flow in developing water supplies. Under his influence Germany became the leading country in supplying the cities with ground*  
715 *water. The results of his work appeared in a number of papers, the first in 1870"*. Hence, we may assume that Meinzer was,  
716 since at least 1928, aware of the Thiem method based on Thiem (1906) and Thiem (1870). The Wenzel (1936) Water-Supply  
717 Paper 679A effectively established the Thiem (1906) method as a standard for permeability assessment of pumping tests and  
718 received broad uptake. In the acknowledgement of Wenzel (1936), Leland Wenzel thanks Günther Thiem for his criticism of  
719 the manuscript, which shows the existence of contacts between Thiem and the USGS at least during the 1930's.  
720  
721 It took between 66 and 30 years after respectively Thiem (1870) and Thiem (1906) until the Thiem type of pumping test was  
722 introduced and made popular in the US. Although Meinzer (1925, 1928) realized the importance of compressibility and  
723 elasticity of aquifers in the 1920's, the dominant groundwater flow theory was steady state and dictated by the Dupuit-Thiem  
724 model until Theis published his transient solution in 1935 (Theis, 1935; Deming, 2002). The slow acceptance of the Theis  
725 equation (in part by Meinzer) meant that by 1936 the USGS Water-Supply Paper 679-A still could widely introduce and make  
726 the Thiem method popular in the US.  
727  
728 To investigate in more detail the contacts between Günther Thiem and the USGS, we requested a search of the US National  
729 Archives, resulting in about 42 pages of relevant correspondence, mainly between Günther Thiem and Oscar Edward Meinzer  
730 dated between 1 December 1936 and 23 August 1940 (USGS, 1936-1940). The correspondence consists of 17 letters from  
731 Thiem to Meinzer and one to Dr Fleming, 13 letters from Meinzer to Thiem, one from Dr Fleming to Thiem, one from the  
732 Chief Clerk to Thiem, and a copy of a publication about Thiem 65 years old (Anonymous, 1935). Thiem writes in German to  
733 Meinzer, while Meinzer writes back in English. However, it is clear that both have a good command of the other language. Of

734 the 17 letters of Thiem, only three seem to have been translated. The first letter (USGS, 1936-1940, Thiem to Meinzer, 1  
735 December, 1936) appears to have been translated by Meinzer himself in handwritten notes on the letter of Thiem (Fig. 11).  
736 The second and third translated letters (USGS, 1936-1940, Thiem to Meinzer, 23 April, 1938 and 31 July, 1939) are typewritten  
737 with the likely purpose of transferring them to a colleague. Some remarks by Thiem concerning the (upcoming) war in Europe  
738 receive particular interest and are translated in English on the original letters in Meinzer's handwriting: "*I hope that more*  
739 *peaceful time will soon come and that the scientific exchange will no longer be obstructed*" (USGS, 1936-1940, Thiem to  
740 Meinzer, 3 November, 1939) and "*We all hope that the light of peace will come to Europe from America. Then I will actually*  
741 *make my trip to America which I have had to give up.*" (USGS, 1936-1940, Thiem to Meinzer, 28 February, 1940).

742

743 It follows from the letters that one or more letters are probably missing and that there might have been correspondence before  
744 the first letter (USGS, 1936-1940, Thiem to Meinzer, 1 December, 1936). In this 'first' letter (Fig. 11), Thiem wrote, as  
745 translated by Meinzer: "*So you have returned safely to America with your esteemed wife! You have seen the birthplace of your*  
746 *parents and have said to yourself how much has occurred since your parents emigrated to the present time. I am glad that you*  
747 *took back with you good impressions of your European journey. You will certainly think back over it often. Mother Europe is*  
748 *indeed very beautiful, but she is also very tired, if one may be permitted to say so. Your country on the contrary is young and*  
749 *full of development possibilities.*" (USGS, 1936-1940, Thiem to Meinzer, 1 December, 1936). Thiem further wrote that he was  
750 sorry that he could not travel to Edinburgh (for the 1936 International Union of Geodesy and Geophysics (IUGG) General  
751 Assembly), as he had hardly any money. Thiem noted that Meinzer travelled to Nancy to see Thiem's good old friend Prof.  
752 Imbeaux, a former president of the Commission on Subterranean Water of the IASH-IUGG. Thiem thanked Meinzer that he  
753 would send some additional copies of Water-Supply Paper 679-A (i.e. Wenzel, 1936). He also wrote: "*Recently I made the*  
754 *acquaintance of the men in the American Institute in Berlin. They were very friendly and lovable, and my wife had to see the*  
755 *institute. These gentlemen also want to get me some copies of this paper. The demand for it is great, especially from many*  
756 *geological institutions in Germany that are not able to send money because of governmental restrictions.*" (USGS, 1936-1940,  
757 Thiem to Meinzer, 1 December, 1936). In closing the letter, Thiem remarked: "*Please tell your esteemed wife many heart*  
758 *greetings from me and my wife. It was a fine afternoon when you took tea with us. Many thanks for the journey<sup>1</sup> photos. I find*  
759 *them excellent and they will be for me a dear reminder. May you keep real well, and have a happy Xmas; and don't forget*  
760 *your old professional comrade, who greets you many times.*" (USGS, 1936-1940, Thiem to Meinzer, 1 December, 1936).

---

<sup>1</sup> Here Mr Meinzer makes an (understandable) translation error; the original in German reads 'reizenden', which means 'lovely', however Meinzer confuses it with 'reisen', which means 'to travel'.

Herrn

O. E. Meinzer,

2923 South Dakota Avenue NE  
Washington USA

*My dear Mr. Meinzer: So you have returned safely to America with your esteemed wife. You have seen the birthplace of your parents, and you will know how much has occurred since your parents emigrated to the present time. I am glad that you took back with you good impressions of your European journey. You will certainly think back over it often. Mother Europe is indeed very beautiful, but she is also very tired, if one only looks at the country on the contrary is young and full of development possibilities.*

*I was very sorry that I could not journey to Edinburgh, but I had hardly sufficient money. You saw Prof. Imbeaux in Nancy, she is to me an old and dear friend, to whom I have been greatly attached, and he had a*

*great fund of knowledge. I thank you very much that you will send me some additional copies of W.S.P. 679 A. Recently I made the acquaintance of the men in the American Institute in Berlin. They were very friendly and*

Mein lieber Herr Meinzer!  
Sie sind also glücklich mit Ihrer Frau Gemahlin nach Amerika zurückgekehrt! Sie haben die Heimat Ihrer Eltern gesehen und werden sich gesagt haben, was sich alles inzwischen ereignet hat zwischen der Auswanderung ihrer Eltern und der heutigen Zeit. Es freut mich, dass Sie gute und nachhaltige Eindrücke von Ihrer Europa-Reise mit nach Haus genommen haben; Sie werden sicherlich oft daran zurückdenken. Die Mutter Europa ist wohl sehr schön, sie ist aber auch sehr müde, wenn man so sagen darf; Ihr Land hingegen ist ein junges Land voller Entwicklungsmöglichkeiten.

*Ich* Es war sehr traurig, dass ich nicht nach Edinburgh fahren konnte, doch hätte ich kaum Geld gehabt. Sie haben den Herrn Prof. Imbeaux in Nancy gesehen; er ist mir ein alter lieber Freund, an dem ich sehr geblieben habe und er verfügt über ein grosses Wissen.

761

762 Figure 11: First page of a typewritten letter by Günther Thiem with hand-written translation by Oscar Meinzer (USGS, 1936-1940,  
763 Thiem to Meinzer, 1 December, 1936).

764

765 Oscar Edward Meinzer was born November 28, 1876, on a farm near Davis, Illinois (Sayre, 1948, 1949b). He was one of six  
766 children of William and Mary Julia Meinzer, born in Karlsruhe, Germany. His grandparents and parents emigrated to escape  
767 a culture, which they considered oppressive. *“This may have directly influenced Meinzer’s future religious convictions,*  
768 *independent thought, hatred of war, and industriousness.”* (Reuss, 2000). The European travel of Meinzer took place in 1936.  
769 He travelled to the IUGG Assembly at Edinburgh, Scotland, but he also visited hydrologists in Germany, Holland and France  
770 (Meinzer, 1936: a 4-page trip report, however it was not published and we have not been able to obtain a copy; Waring and  
771 Meinzer, 1947; Sayre, 1949a). In the interview of C.V. Theis, CV must have been confused about Meinzer bringing back from  
772 this trip the idea of doing a Thiem method pumping test, as the pumping test was executed in 1931 and as there is no indication  
773 that Meinzer made an earlier trip to Europe than 1936 (Sayre, 1949a). Meinzer was the first chairman (1930) of the Hydrology  
774 Section of the American Geophysical Union (AGU), which served as the American National Committee of the IUGG (Meinzer,  
775 1931). He was also from 1936-1948 president of the Commission on Subterranean Water of the IASH-IUGG, from 1947-1948  
776 president of the AGU and as such, he was active in the organization of the IUGG 1936, 1939 and 1948 Assemblies. He  
777 anticipated a second Europe trip to attend the Oslo 1948 IUGG meeting before he passed away (Sayre, 1949a).

778

779 Most of the correspondence of Thiem and Meinzer between April 23, 1938, and August 23, 1940, related to a possible  
780 participation of Thiem and a contribution to the IUGG 7<sup>th</sup> Assembly, Washington D.C, September 4-15, 1939. Thiem asked  
781 Meinzer for an invitation to participate in the Assembly (USGS, 1936-1940, Thiem to Meinzer, 23 April, 1938), as normally,  
782 these invitations only went to the official institutes and not to independent hydrological scientists like him. Thiem also  
783 expressed his concern if the German government would provide him with the necessary foreign currency (USGS, 1936-1940,  
784 Thiem to Meinzer, 7 January, 1939). Meinzer replied that he is happy to note that Thiem and his wife are definitely planning  
785 to come to the US, *“We will do all that we can to make your visit pleasant and profitable”* and *“As you know, Mr Wenzel has*  
786 *done a large amount of work on different methods of determining permeability and flow of ground water so that your contact*  
787 *with him will be mutually helpful.”* (USGS, 1936-1940, Meinzer to Thiem, 24 May, 1938 and 23 January 1939). He sends a  
788 copy of the last letter to Prof. Frolow and Dr. Fleming, the latter General Secretary of the American Geophysical Union and  
789 organizer of IUGG 1939 Assembly, and adds a message to Dr Fleming: *“Dr. Thiem indicates his intention to come to the*  
790 *Washington meeting and to bring his wife with him, provided he can make the necessary arrangements with the German*  
791 *government. It is obvious to me that he does not stand in very well with the official representatives of Germany but we in this*  
792 *country esteem him very highly.”* (USGS, 1936-1940, Meinzer to Thiem, 23 January 1939). Meinzer asked Thiem to contribute  
793 to Question No. 3 of the International Commission on Subterranean Water: ‘Determination of runoff and physical conditions  
794 of the flow of underground water in natural or altered ground, the flow being natural or induced’ of the forthcoming meeting  
795 (USGS, 1936-1940, Meinzer to Thiem, 28 November 1938). This question was coordinated by Leland Wenzel of the USGS.  
796 Thiem submitted via the official channel of Dr. Koehne of the ‘Landesanstalt für Gewässerkunde’ in Berlin (Koehne, 1939)  
797 his written contribution *“Berechnete und beobachtete Grundwassermengen”* (Thiem, 1939c, 1940d). Meinzer’s reaction was:  
798 *“Your paper on Question No. 3 with introduction by Dr. Koehne was received a long time ago and is being pre-published for*

799 *the Washington meeting. Mr. Wenzel and I have read it in part and he will include it in his general report. We find it very*  
800 *interesting.”* (USGS, 1936-1940, Meinzer to Thiem, 29 June 1939).

801

802 July, 1939, Thiem reported to Dr Fleming, who forwarded a translation to Dr Meinzer, about his suffering for weeks: “*My*  
803 *health has not yet fully improved, for I am suffering in my right knee from rheumatism of the joints so that I cannot bear much*  
804 *weight on it. Also I have trouble going up stairs. [...]You cannot imagine how much my refusal (of your invitation) distresses*  
805 *me.”* (USGS, 1936-1940, Thiem to Fleming, 31 July, 1939). Meinzer replied: “*I regret very much that the condition of your*  
806 *health will prevent your attending and taking part in the meetings of the Union. As you know, I had anticipated with pleasure*  
807 *meeting you again and discussing with you personally hydrologic problems of mutual interest.”* He also noted that he translated  
808 Thiem’s Assembly paper into English for use at the meeting (USGS, 1936-1940, Meinzer to Thiem, 31 August, 1939).

809

810 Three days after the Washington meeting, Meinzer reported to Thiem: “*...although most of the European delegates were not*  
811 *able to attend the meeting in Washington, a considerable number of representative delegates from different countries were*  
812 *nevertheless able to attend and the meeting was very successful. In the Commission on Subterranean Water a total of 55 papers*  
813 *were in hand in either printed or typewritten form, and these were effectively reviewed by the general reporters. The relatively*  
814 *few authors who were present were called upon to present their own papers at greater length. The only one of the officers of*  
815 *the Association who was able to attend was Vice-President Slettenmark who served efficiently as the President during the*  
816 *meetings. President Lutschg’s Presidential address, which was submitted in German, was translated and presented by Mr.*  
817 *Slettenmark in the English language. It was accompanied by beautiful lantern slides. We all regretted that you and the other*  
818 *German delegates were not able to attend.”* (USGS, 1936-1940, Meinzer to Thiem, 18 September, 1939).

819

820 Wenzel (1939) provided a summary on the contributions of Question 3, while Meinzer (1939) reported on Question no. 2:  
821 ‘Definitions of the different kinds of subterranean water’. Official reports of the Assembly, which took place under the  
822 emerging clouds of WWII, are provided in Chapman (1939) and Fleming (1940); “*On August 30, when the European political*  
823 *crises was at its height, it was decided... that the Assembly should be held as scheduled but that its activities should be confined*  
824 *to scientific matters only”*. The IUGG President la Cour closed the Assembly with the words “*...it has been an extremely*  
825 *important meeting, furthering our science and showing to the world a battlefield where only victory can be recorded because*  
826 *even the overthrow of a theory is a victory for truth”* (Fleming, 1940).

827

828 January, 1940, Thiem wrote to Meinzer that he received a package with extensive documents of the meeting in Washington  
829 and that he now he really regretted that he could not participate. He also noted that he translated into German the Question 3  
830 report of Wenzel (1939) and will publish it in a German professional journal (USGS, 1936-1940, Thiem to Meinzer, 6 January,  
831 1940), which he indeed did (Wenzel, 1940). He continued: “*It is for me a special recognition that the Thiem method for the*  
832 *estimation of the hydraulic conductivity of the subsurface and its water discharge in your country is applied. Do you think,*

833 *that it later would be suitable to present myself in America to undertake there hydrological investigations for groundwater*  
834 *supply for cities based on my method? I would be very willing to come to America. I would like to ask you to tell me to whom*  
835 *I should direct myself in this case or do you think that your office could take on the negotiation for my appointment as expert?*  
836 *However, these questions can only be discussed with successful prospect when normal times in Europe, let alone in the world,*  
837 *have set in again.”* (USGS, 1936-1940, Thiem to Meinzer, 6 January, 1940). Meinzer replied to Thiem that he would like to  
838 have a copy of the translated report, and “*We would be glad to have a visit from you at any time. However, I would not wish*  
839 *to encourage you as to the prospects of obtaining professional work in this country. You might be able to make a success of*  
840 *such an undertaking but there are so many difficulties in establishing oneself in a new country that I do not feel at all sure as*  
841 *to the success that you might have.”* (USGS, 1936-1940, Meinzer to Thiem, 1 February, 1940). Meinzer was friendly, but he  
842 definitely discouraged Thiem from working in the US.

843

844 The last letter in the correspondence is from Thiem to Meinzer in August, 1940. Meinzer translated the following lines: “*Your*  
845 *friendly letter of April 17 was received by me on Aug. 20 ... I suppose you will not receive my letter till Christmas. Therefore*  
846 *I will already today wish you a merry Christmas. My wife and I send our best greetings to you and your wife. Auf Wiedersehen*  
847 *either in America or Europe. Yours Dr Engineer G. Thiem.”* (USGS, 1936-1940, Thiem to Meinzer, 23 August, 1940). It is  
848 not known if the correspondence ceased or continued during or after WWII. However, in 1946 shortly after WWII, Meinzer  
849 retired as Geologist in Charge of the Division of Ground Water. He died June 14, 1948, rather suddenly while taking an  
850 afternoon nap, aged 71 (Sayre, 1948).

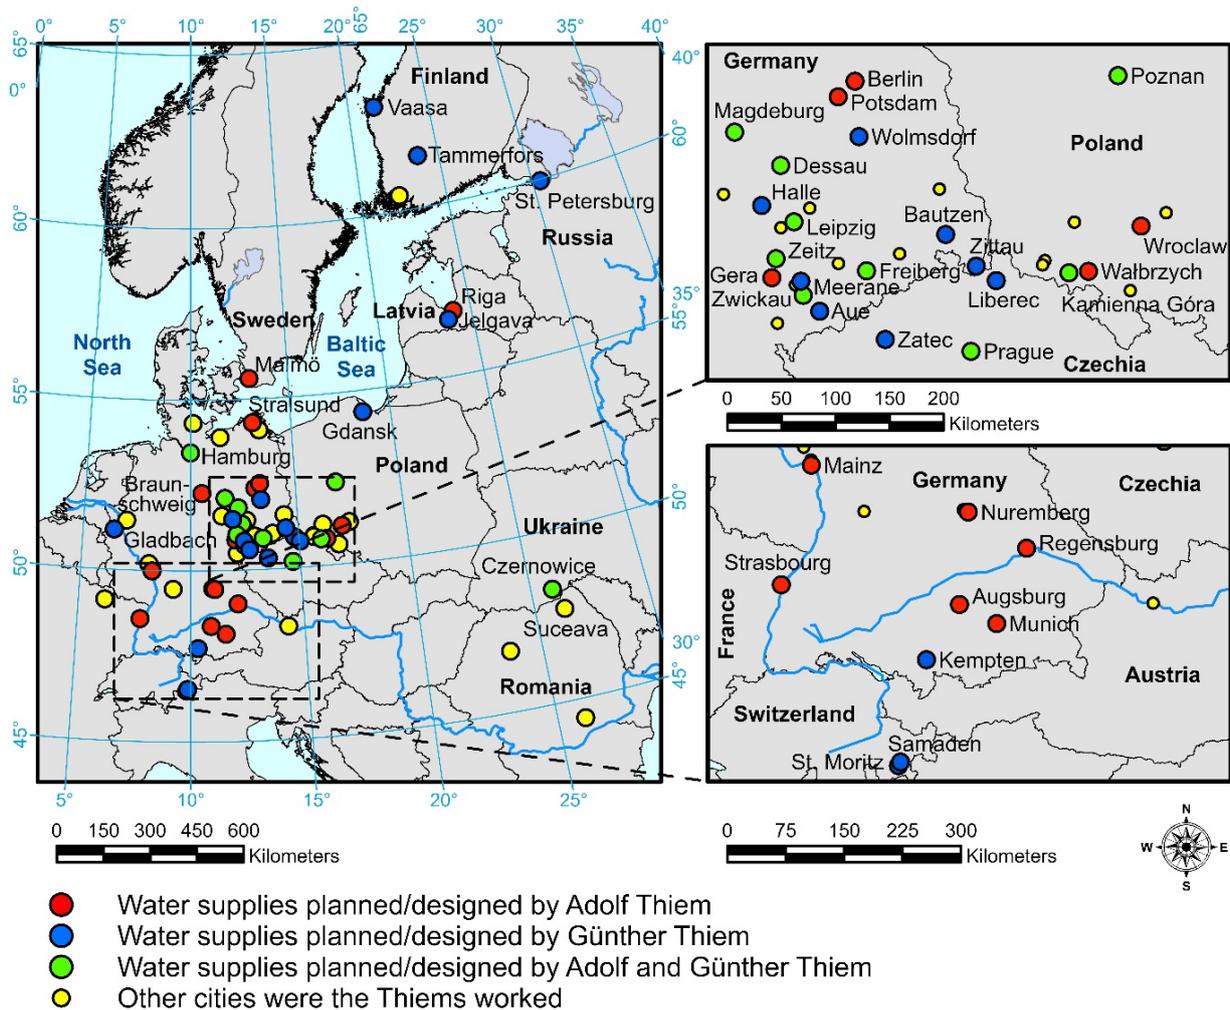

851

852 In the 1949 address book of Leipzig, Thiem is listed as “*Beratender Ingenieur für Wasser und Abwasser, Stadtrat a.D.*”  
853 (Consulting engineer for water and waste water, formerly member of city council), still living in Hillerstraße 9. According to  
854 Grahmann (1960), Günther Thiem was active until his death in Leipzig on August 31, 1959, aged 83.

## 855 **5 Conclusions**

856 Forever, the name Thiem will be connected to the Dupuit-Thiem equation, the first practical model for pump test analysis.  
857 However, father and son Thiem were far more prolific contributors to the canon of methods currently used in hydrogeology  
858 than most people know. All of their method development was done out of practical need, which arose during their many  
859 projects while devising solutions for the many problems they were facing building water supply schemes from scratch. This is  
860 even more remarkable since it was done besides running a successful consulting business and planning many water supply  
861 schemes all over Europe, which today can be found in Germany, Poland, the Czech Republic, Austria, Switzerland, France,  
862 Finland, Sweden, Latvia, Romania, Ukraine and Russia (Fig. 12). The infrastructure they planned and designed is a lasting  
863 legacy since some of their water works are still active today after often more than 100 years, albeit in modernized form (Fig.  
864 13, 14). A few buildings have been preserved as protected monuments, e.g. in Leipzig and Suceava. The most striking buildings

865 are, of course, the water towers, e.g. in Leipzig (Probstheida, Möckern, Großschocher), Markranstädt (1895), Liebertwolkwitz  
 866 (1904, now used for housing), Olesnica (1898, then Oels), and Strasbourg (1878, now a museum of voodoo).  
 867

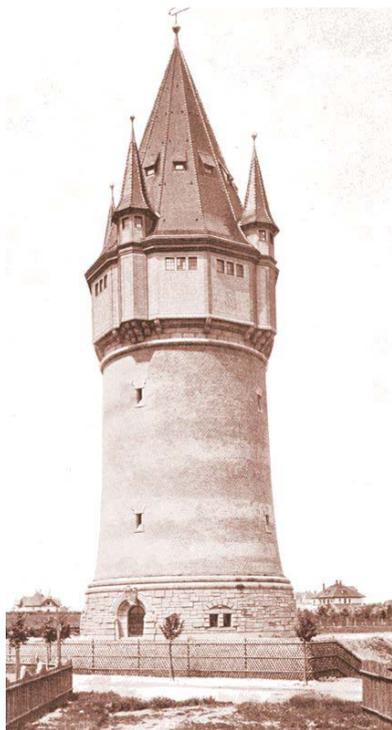

869 **Figure 12: Map of water works planned and designed by Adolf and Günther Thiem.**

870

871 While most of the Thiem methods, such as isopotential maps, tracer tests and screened vertical wells were devised by Adolf  
 872 Thiem, who was a true explorer and inventor, it was Günther's role to perfect and propagate them, even in the turmoils of two  
 873 world wars and several regime changes. Considering the cumbersome communication channels of the late 19<sup>th</sup> and early 20<sup>th</sup>  
 874 century and the language barriers of that time, it is amazing to see that both Thiems were in close contact with many leading  
 875 scientists from Europe and abroad. The field was small, and the members were well aware of the work of each other;  
 876 publications in different languages did not seem to be a barrier. Especially Günther's contacts to Oscar Meinzer of the USGS

877 led to the introduction of their methods into the repertoire of English-speaking hydrogeologists. Meinzer's international  
878 contacts and his (German) language skills have played a crucial role in the exchange of the strongly developing science of  
879 groundwater hydrology.  
880

881 **Figure 13: The Probstheida water works, Leipzig, planned and designed by Adolf Thiem: (above) aerial view with the water tower**  
882 **(foreground left) and water storage cellars with grass cover, the tower of the Völkerschlacht Monument is visible in the background,**  
883 **the small tower to its left is part of the chapel of the Südfriedhof where the Thiem family grave is located, (lower left) water tower**  
884 **in its original shape, around 1907, the roof was damaged in WW II and rebuilt in simplified forms, (lower right): inside of water**  
885 **storage cellar (Photos: Leipziger Gruppe, with permission).**

886

887 **Figure 14: Buildings and pumps of the Canitz water works then and now, Leipzig: (left) as planned and designed by Adolf and**  
888 **Günther Thiem, status 1912, (right): status today (Photos: Leipziger Gruppe, with permission).**

889

890 Both Adolf and Günther Thiem were highly concerned with the practical applicability of their theoretical work and with  
891 presenting it in a way that non-experts could follow their argumentations. In his study for the water supply of Riga, Adolf  
892 Thiem stated that *“Es war mir nicht darum zu tun, Behauptungen und Schlüsse lediglich vom Standpunkt de Fachmannes*  
893 *aufzustellen, sondern ich beabsichtige vielmehr, auch dem außerhalb des Fachs stehenden Leser den logischen Gang der*  
894 *Untersuchungen klarzulegen und ihn so in die Lage zu versetzen, meine Methode kritisch prüfen zu können. (It was not my*

895 *intention to present my claims and conclusions solely from the point of view of an expert, but to clearly show to a reader, who*  
896 *is not from the field, the logical structure of my investigations, enabling him to critically judge my method)*“ (Thiem 1883b).

897

898 The engineering work of the Thiems can only be understood in the light of the social and technical problems arising during  
899 the late 19th and the early 20th century. Increasing population, industrialization and urbanization had increased the water  
900 demand but – at the same time – had negatively affected water quality. Groundwater came into focus as a safe, reliable and  
901 often abundant resource to overcome both the demand for a sufficient quantity of water and for improved hygiene by better  
902 water quality. However, little was known about this mysterious underground resource. The Thiems reacted to this societal  
903 problem by adaption of current technology but also by innovation, e.g. the development of new techniques and methods. One  
904 example is the vertical well, which design they improved continuously over several decades, paving the way towards the  
905 modern-day wells. At the same time, they were early adopters of new technology (e.g. the pumps driven by steam engines  
906 used in pumping tests) and new, mass-produced materials (e.g. steel and copper used for wells). Both Thiems were also great  
907 educators and their wealth of publications and presentations shows their tireless dedication to the improvement of water supply.  
908

909 In the 19<sup>th</sup> century, the German states and speaking countries saw a professionalization of the engineering industry, the  
910 development of an independent technical educational system and increasing specialization of engineering disciplines (König,  
911 2016; Weber, 2020). Professional organizations developed strongly and published many specialized journals (Weber, 2020).  
912 Günther Thiem’s editorial activity is a great example of this broader trend in the engineering discipline. Engineers were trained  
913 at Technische Hochschulen (institutes of technology), all other professions were trained at the universities, which had a much  
914 longer tradition. The role of the ‘Technische Hochschulen’ was to provide a labour force for the strongly developing industry  
915 (Picon, 2004). Only around 1900 the Technische Hochschulen were allowed to confer PhDs (König, 2016). While Adolf Thiem  
916 was an autodidact, Günther Thiem was one of the first with his 1906 PhD from the Königlich Technische Hochschule (Royal  
917 Technical University) in Stuttgart. Hence, the engineering work of the Thiems was in response to the rapidly changing times  
918 in which they were living. However, equally, they benefitted strongly from the developing engineering profession and  
919 approaches, providing opportunities for experimenting and creating solutions for societal problems.

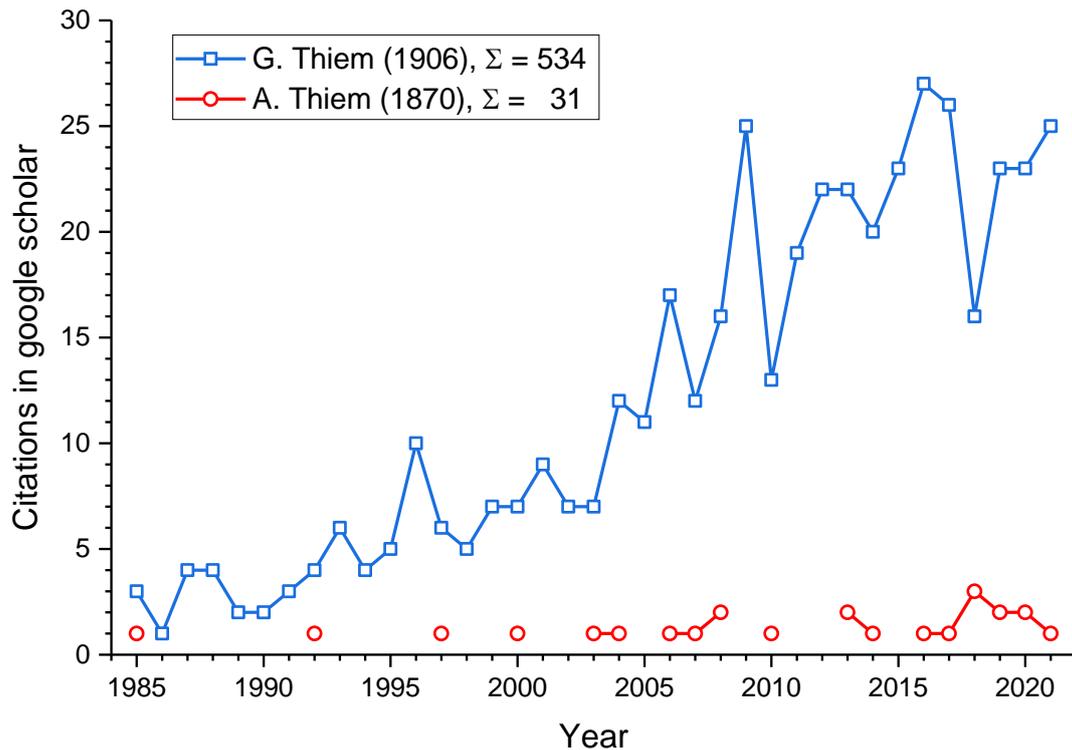

920

921 The lives and work of Adolf and Günther Thiem are not only documented in their legacy of references, of which we have tried  
922 to collect and list as many as possible. Several museums hold collections containing reports, letters and photographs. These  
923 include: the archives of the Deutsches Museum (<https://www.deutsches-museum.de/en/library/searches/>), the Sächsisches  
924 Staatsarchiv (Saxonian State Archive), Dresden and the Museum der Leipziger Stadtgeschichte (Museum of City History),  
925 Leipzig.

926

927 Although many hydrogeologists today are using the methods developed by the Thiems, albeit often unbeknownst, their legacy  
928 is not forgotten. According to google scholar (accessed on May 17, 2022), the 1906 PhD thesis of Günther Thiem has been

929 cited 534 times, usually as a reference for the Thiem method for pumping tests. Figure 15 shows that its citations have increased  
 930 steadily over the last decades, and the paper can well be considered to be a cornerstone of hydrogeological literature. It should  
 931 be noted that the almost linear increase in its citations is a mirror image of the continuous rise in the number of groundwater-  
 932 related publications over the last decades, which have experienced annual growth rates of around 10% since the late 1970s (Jia  
 933 et al. 2020). Nevertheless, the fact that such an old publication can keep up with the high modern pace of citations is a legacy  
 934 of its importance. Ironically, Adolf Thiem's seminal 1870 paper, which contains the actual Thiem equation, only stands at 31  
 935 citations and only pops up randomly, often in literature from Germany (Fig. 15).  
 936

937

938 **Figure 15: Citations of the two seminal papers by Adolf and Günther Thiem (Thiem 1870, Thiem 1906), according to google scholar**  
 939 **(accessed May 17, 2022).**

940

941

## 942 **Acknowledgements**

943 The authors would like to thank to Herfried Apel, a grandson of Adolf Thiem's oldest son Paul Adolf Thiem, for providing  
944 access to important information on the Thiem family, including the family tree. We also express our gratitude to the Leipziger  
945 Gruppe for providing photographs of the buildings shown in Figure 13 and 14.
