Abstract. Climate change is projected to increase flood risks in West Africa. The EU Horizon 2020 project FANFAR co-designed a pre-operational flood forecasting and alert system for West Africa in four workshops with 50–60 stakeholders from 17 countries, adopting a Multi-Criteria Decision Analysis (MCDA) process. Firstly, we aimed to find a robust configuration of the FANFAR system. We document empirical evidence of MCDA, including stakeholder analysis, jointly creating 10 objectives, and 11 FANFAR system configurations. Stakeholders found it most important that the system produces accurate, clear, and accessible flood risk information, well before floods. Monte Carlo simulation and sensitivity analyses helped identifying three configurations that were robust despite uncertainty of expert predictions and different stakeholder preferences, elicited in group sessions. Secondly, we investigated if problem structuring helps focus early technical system development. Although partly achieved, full MCDA was necessary to provide convincingly robust configurations. Thirdly, we critically analyzed MCDA based on literature from sustainability science and transdisciplinary research. Our proposed framework consists of three steps: co-design (joint problem framing), co-production (doing research), and co-dissemination and evaluation of integrated knowledge. MCDA met many requirements, but not all. In step 1, participatory MCDA with problem structuring provides a consistent methodology, and can identify stakeholders and shared objectives to foster joint understanding. MCDA successfully contributes to step 2 by combining interdisciplinary expert knowledge, integrating conflicting stakeholder preferences, handling uncertainty, and providing unambiguous, shared results. Many elements of step 3 are not met by MCDA. We discuss this framework and using MCDA for transdisciplinary hydrology research that engages with stakeholders and society.

1 Introduction

25 1.1 Floods in West Africa

West Africa is vulnerable to the projected impacts of climate change, particularly related to runoff quantities (Aich et al., 2016; Roudier et al., 2014). While the mechanisms and projections remain uncertain for West Africa, there is growing evidence for increased frequency, magnitude, and impact of fluvial floods (Nka et al., 2015). West Africa is already heavily impacted by floods. Preliminary data from the United Nations estimate that 465 people died from floods in West and Central Africa in

30 2020. More than 1.7 million people were affected (double the number of 2019), 94'000 people were displaced, and 152'000
houses were destroyed (OCHA, 2020). Worldwide, good operational flood forecast systems, giving accurate, timely, precise,
and understandable forecast information and alerts, provide effective and affordable help to anticipate and minimize flood
impacts (Perera et al., 2019). Several systems have been set up for different West African regions, some being very useful.
However, none seem to sufficiently meet stakeholder needs regarding: i) timeliness (e.g., annual frequency of the PRESASS
35 and PRESAGG seasonal forecasts; WMO, 2021); ii) coverage (e.g., systems propagating streamflow measurements such as
SLAPIDS, OPIDIN, FEWS-Oti often only cover a small part of West Africa and do not predict in ungauged basins; Massazza
et al., 2020); iii) up-to-date operational production because many models are used only for research (e.g., Aich et al.,
2016;Schuol et al., 2008), and sometimes systems fail due to e.g., interrupted data flows or server failures (e.g., SATH-NBA
in the major 2020 floods; NBA, 2020); iv) accuracy (e.g., global modelling systems such as GloFAS; Passerotti et al., 2020);
40 and v) openness and ownership (e.g., proprietary closed source consultancy systems, which may limit the capacity and inde-
pendence of West African scientists and practitioners, and hence the systems' long-term sustainability).

1.2 The FANFAR project

The EU Horizon 2020 project FANFAR, running from 2018 to 2021 addresses these gaps (FANFAR, 2021). FANFAR oper-
ates in a transnational and transcontinental context, with consortium partners across Europe (Italy, Spain, Sweden, and Swit-
45 zerland) and Africa (organizations AGRHYMET and NIHSA). It includes stakeholders across 17 countries of West and Central
Africa. FANFAR establishes and reinforces existing cooperation between European and West African hydrologists, infor-
mation and communication technology (ICT) experts, decision analysts, and end users such as West African hydrologists and
emergency managers (Andersson et al., 2020a) to co-develop a pre-operational flood forecasting and alert system at West
Africa scale ("FANFAR system"). It is currently based on three open-source hydrological models, Niger-HYPE, West Africa
50 HYPE, and World-Wide HYPE (Andersson et al., 2017;Arheimer et al., 2020), employed in a cloud-based ICT environment.
The daily forecasting chain includes meteorological reanalysis and forecasting, data assimilation of gauge observations and
satellite altimetry, hydrological initialization and forecasting, flood alert derivation, and distribution through Email, SMS, API,
and a web based Interactive Visualization Portal (IVP, <https://fanfar.eu/ivp/>). In this paper, we do not address the technical
system and refer interested readers to Andersson et al. (2020b). Rather, we emphasize the complex development of the FAN-
55 FAR system in an iterative co-design process, the necessity of which has been recently underlined by Sultan et al. (2020). At
its core are three one-week workshops carried out in West Africa from 2018–2020, each with 50–60 participants, and online
workshops in 2021. We organized stakeholder participation adopting a comprehensive Multi-Criteria Decision Analysis
(MCDA) process (Belton and Stewart, 2002;Eisenführ et al., 2010;Keeney, 1982) that includes problem structuring methods
(PSMs; Rosenhead and Mingers, 2001). Using MCDA, we integrated the stakeholders' preferences in the expert assessment
60 of how well different FANFAR system configurations meet stakeholder objectives. Ideally, this helps focus system develop-
ment on configurations that best meet expectations, given the possibility of contradictory interests concerning the importance
of objectives, and uncertainty about how well a system configuration can achieve the objectives.

MCDA has been used in flood risk management (reviewed by de Brito and Evers, 2016;Abdullah et al., 2021), but rarely focusing on a participatory stakeholder process. Stakeholders were not even mentioned in a review of 149 papers (Abdullah et al., 2021). The other review concluded that stakeholder participation was fragmented, despite being reported in 51% of 128 papers, i.e., stakeholders only assigned importance weights to objectives, but were not involved in the entire decision process (de Brito and Evers, 2016). Participatory processes involving researchers and non-scientific actors are extensively discussed in literature from sustainability sciences (e.g., Caniglia et al., 2021;Norstrom et al., 2020) and transdisciplinary research (e.g., Jahn et al., 2012;Lang et al., 2012;Mauser et al., 2013;Schneider et al., 2019;Wuelser et al., 2021). With this paper we combine two fields. We draw from this literature emphasizing continuous stakeholder participation to achieve societal transformation. We use MCDA as integrative methodological process, which in flood risk management seems to have been mainly used as a technical method, without broader stakeholder participation (de Brito and Evers, 2016). To the best of our knowledge, we are not aware of systematic assessment of MCDA processes from the angle of transdisciplinary sustainability research.

1.3 Aims, research questions, and structure of paper

The aim of the FANFAR project is to co-design and co-develop a pre-operational flood forecasting and alert system at West Africa scale. For the stakeholders in West Africa, and ultimately for thousands of people affected by floods, it is of prime importance to find a good configuration of a flood forecast and alert system. “Good” means that it satisfies the main needs of those that are meant to use it: the hydrological services and emergency management agencies (Research Question A; RQA). Moreover, there was a timing issue. The IT specialists and hydrologists could not wait with technical system development until all stakeholder information had been gathered and analyzed with MCDA. We thus needed to rely on preliminary information early in the project, which was refined as the project progressed (RQB). This leads to following research questions:

- **RQA:** What characterizes a good regional flood forecasting and alert system for West Africa? Is it possible to identify a robust FANFAR system configuration, despite uncertainty (of expert predictions about FANFAR system performance and MCDA model) and possibly different preferences of stakeholders regarding what the system should achieve?
- **RQB:** How can problem structuring at the beginning of the project help focus the development of the FANFAR system to meet the stakeholders’ expectations (i.e., before MCDA results are available)?

According to the call of this Special Issue: “(...) we need to remind ourselves that a scientific decade on change in hydrology and society requires the perspectives of those disciplines that have traditionally been concerned with society (...). While interdisciplinary conversations have been happening to some extent, transdisciplinary endeavors remain largely undocumented” (Carr et al., 2021). We aimed to document empirical evidence from the FANFAR project, contributing to knowledge production, learning, and scientific praxis in hydrology. Taking a more theoretical stance, we aimed to critically analyze FANFAR from the perspective of knowledge co-creation, sustainability science, and transdisciplinary research. We focused on MCDA as a process, rather than a technical method (sect. 2.2; Figure 1). We set up a framework drawing from literature to uncover strengths and weaknesses of MCDA to guide the transdisciplinary process (RQC). We summarized insights and recommendations of special interest to hydrology praxis when engaging with stakeholders (RQD). The specific research questions are:

- **RQC:** How suitable is a structured, participatory decision analysis process based on MCDA for guiding large transdisciplinary projects? What worked well or less well in FANFAR? Could interests of a large number of stakeholders be integrated?
- **RQD:** Is the proposed framework useful for this type of evaluation? What insights and recommendations can we provide for future transdisciplinary projects in hydrology research?

100 The paper is organized as follows: In the Methods, we review main elements of frameworks in the sustainability science and transdisciplinary research literature (sect. 2.1), followed by a framework proposition (sect. 2.1.1). We shortly review literature on MCDA in flood risk management (2.2.1) and motivate using MCDA to structure stakeholder participation (sect. 2.2.2). We present the workshops in West Africa (sect. 2.2.3), and the methods in each MCDA step (sects. 2.2.4 – 2.2.11). In the Results (sect. 3), we present problem structuring steps of MCDA including stakeholder analysis, the final MCDA results, and sensitivity analyses to test robustness of best performing FANFAR system configurations under changing model assumptions. The Discussion follows the research questions: finding a robust FANFAR system configuration with MCDA (RQA, sect. 4.1) and whether early problem structuring helped system design (RQB, sect. 4.2). We analyze MCDA following the proposed framework of transdisciplinary research (RQC, sect. 4.3). We conclude by summarizing insights regarding the framework and recommendations for using an MCDA process in hydrology research, engaging with stakeholders and society (RQD; sect. 5).

110 2 Methods

2.1 Sustainability science and transdisciplinary research frameworks

Disaster management increasingly acknowledges that developing early warning systems should closely involve users to increase the systems' usefulness (adapted to user needs) and effectiveness (e.g., enhance uptake; Basher, 2006; Bierens et al., 2020; UNISDR, 2010). This follows a trend calling for “collaborative action”, “collaborative governance”, and “co-production of knowledge” in many fields, e.g., healthcare (Donetto et al., 2015). Sustainability science stresses that societal transformation is needed to address today's global environmental challenges. This requires close engagement of academia with societal actors to co-produce and integrate knowledge (e.g., Caniglia et al., 2021; Lang et al., 2012; Mauser et al., 2013; Norstrom et al., 2020; Schneider et al., 2019; Wuelser et al., 2021). Transdisciplinary research emphasizes collaboration between different scientific disciplines, and between researchers and practitioners (Jahn et al., 2012). It seeks to support societal problem solving with “situated knowledge” for a specific problem in its socio-ecological context (Wuelser et al., 2021). Many collaborative, transdisciplinary projects involving non-scientific stakeholders are being carried out. However, there is still a lack of systematic integration and conceptualization of empiric evidence (e.g., Lang et al., 2012; Caniglia et al., 2021), and of understanding the extent and mechanisms of advancing sustainability transformations (Schneider et al., 2019; Wuelser et al., 2021).

125 Frameworks for collaborative governance usually consist of stages such as inputs, research processes, direct outputs, and further outcomes (Schneider et al., 2019). Earlier conceptual frameworks stem from transdisciplinary literature. Main phases in such iterative processes are: (i) forming a common research object (see Figure 1 in Jahn et al., 2012), problem framing and

team building (see Figure 1 in Lang et al., 2012); (ii) co-creating solution oriented and transferable knowledge through collaborative research; (iii) applying the co-produced knowledge (Lang et al., 2012), and evaluating its contribution to societal and scientific progress (Jahn et al., 2012). Similar three steps were proposed by an international initiative, where the co-creation of knowledge for addressing global sustainability problems was divided into: (i) co-design; (ii) co-production; and (iii) co-dissemination of knowledge, involving academia and stakeholders throughout (see Figure 3 in Mauser et al., 2013). Co-design includes joint framing of the sustainability challenges faced by society, research definition, and implementation (e.g., funding). Co-production includes methodologically consistent scientific integration of interdisciplinary knowledge, including ways for dealing with the uncertainty of results. The co-produced knowledge should be societally relevant, which is ensured by continuous interaction with stakeholders. Co-dissemination of results includes scientific publications and products that are accessible and understandable by different societal groups. There should be transparent discussion of results, especially among groups of conflicting interests, and consequential action should be taken.

Two recent articles in “Nature Sustainability” propose frameworks sharing similar elements, but with different structuring. Caniglia et al. (2021) suggest that research actions for sustainability create transformative change in three dimensions: (i) knowledge informing intentional design; (ii) knowledge enhancing shared agency by involving multiple actors; and (iii) knowledge enabling contextual realization in constantly changing environments. These are further characterized by prescriptive knowledge (recommendations about more desirable options), co-produced knowledge (through collaborative engagement with actors, incorporating their diverse perspectives and interests), and situated knowledge (tailored to specific contexts; see Table 2 in Caniglia et al., 2021). In a more practical perspective, four guiding principles for evaluating the quality and success of co-production processes were proposed by 36 sustainability researchers, underpinned with examples (see Figure 1 in Norstrom et al., 2020). These are: (i) context-based (situate process in particular context, place, or issue); (ii) pluralistic (recognize multiple ways of knowing and doing); (iii) goal-oriented (articulate clearly defined, shared goals); and (iv) interactive (ongoing learning among actors, active engagement, and frequent interactions).

Recent studies systematically evaluated transdisciplinary projects to identify common characteristics that are re-usable in other cases (Wuelser et al., 2021). Analyzing 12 Swiss transdisciplinary research projects, seven types of transferable knowledge were proposed (see Table 2 in Wuelser et al., 2021): (i) transdisciplinary principles (e.g., take practitioners on board from the start); (ii) transdisciplinary approaches (procedural, e.g., joint problem identification, strategies for building alliances with regional partners); (iii) systematic procedures (e.g., specific methodologies); (iv) product formats (communicate and use research results in practice, e.g., capacity building); (v) experiential know-how (personal learnings, skills, and experiences); (vi) framings (definitions, descriptions of issues); and (vii) insights, data, and information (results, outputs). Similarly, 31 international transdisciplinary projects were systematically analyzed for identifying generic mechanisms of creating societal impacts (see Figure 1 and Table 2 in Schneider et al., 2019). Three distinct mechanisms and seven strategies were identified: (i) promote

160 systems, target, and transformation knowledge (by providing 1. access to information; 2. advice and training; 3. public de-
 bates); (ii) foster social learning for collective action (4. multi-stakeholder groups; 5. North-South partnerships); and (iii) en-
 hance competences for reflective leadership (6. transformative education; 7. communities of practice).

The last example stems from earth systems sciences, using a case study for climate assessment as starting point for conceptual
 insights, rather than firstly drawing from social science theories as most above examples (Lemos and Morehouse, 2005). These
 authors argue for interactive models (= frameworks) and iterative processes to increase innovation and societal impact across
 three dimensions: (i) interdisciplinarity (effort of scientists from different disciplines to tackle complex problems, working
 165 together iteratively, but separately if necessary); (ii) interaction with stakeholders (e.g., problem definition, testing and dis-
 seminating results, adapting research to users' needs, building trust); and (iii) production of usable knowledge.

2.1.1 Evaluation framework for transdisciplinary MCDA process

We use common elements from these frameworks to analyze the transdisciplinary co-design process based on MCDA. We
 emphasize elements that are crucial for the practice-oriented FANFAR project, aiming to produce a user friendly, but techni-
 170 cally complex flood forecast and alert system. Some elements are especially relevant to earth systems sciences, e.g., climate
 assessment (Lemos and Morehouse, 2005), but received less attention in the social science oriented sustainability and trans-
 disciplinary research literature: explicit consideration of uncertainty, and the interdisciplinary effort needed for tackling tech-
 nically complex problems (Lemos and Morehouse, 2005;Mauser et al., 2013). We follow a stepwise timeline, as proposed by
 many (Jahn et al., 2012;Lang et al., 2012;Mauser et al., 2013), using the terminology by Mauser et al. (2013): (i) co-design;
 175 (ii) co-production, and (iii) co-dissemination of knowledge (to which we add evaluation), involving academia and stakeholders
 throughout. For each phase, we include specific elements appropriate for our context (Table 1).

Table 1. Conceptual framework for transdisciplinary research based on literature: (1) co-design, (2) co-production, and (3) co-dissemination of knowledge (terminology from Mauser et al., 2013), used to assess the MCDA process in the FANFAR project.

ID	Step	Explanation	Literature examples
1	Co-design	Joint problem framing	
1a	Build collaborative research team	Include structures enabling participation from the start, e.g., use stakeholder mapping; aim at legitimacy of team; include bridging organizations or knowledge brokers to increase trust	(Lang et al., 2012;Wuelser et al., 2021;Norstrom et al., 2020)
1b	Define research questions, methodological framework	Aim for balanced problem ownership from science and practice; define meaningful, shared goals, and measures of success	(Lang et al., 2012;Mauser et al., 2013;Jahn et al., 2012;Wuelser et al., 2021;Lemos and Morehouse, 2005;Norstrom et al., 2020)
1c	Define boundary object	Translate problem into boundary object that allows re-integrating insights into societal implementation and scientific body of	(Lang et al., 2012;Jahn et al., 2012;Schneider et al., 2019)

knowledge; “transformation knowledge” on how to make
 change e.g., with measures and tools

2.	Co-production	Conducting integrated research to produce new knowledge; continuous exchange among scientists from different disciplines, and with stakeholders	
2a	Apply integrative (scientific) methods	Facilitate differentiation of different bodies of knowledge by using appropriate systematic procedures that ensure methodological consistency of research process	(Mauser et al., 2013;Wuelser et al., 2021;Lang et al., 2012;Jahn et al., 2012)
2b	Interdisciplinary collaboration	Integrate knowledge of scientists from different disciplines; avoid conflicting methodological standards	(Mauser et al., 2013;Lemos and Morehouse, 2005;Jahn et al., 2012;Norstrom et al., 2020)
2c	Explicitly consider uncertainty	Especially relevant in natural science problems addressing long time horizons (e.g., climate change)	(Mauser et al., 2013)
2d	Integrate practice stakeholders in iterative process	Ensure appropriate roles, range of perspectives and skills, and context-based research; avoid discontinuous participation and vagueness of results that conceal potential conflicts	(Caniglia et al., 2021;Lang et al., 2012;Lemos and Morehouse, 2005;Norstrom et al., 2020)
2e	Pluralistic principle/social learning	Create shared understanding across multiple axes (e.g., disciplines, sectors, countries, gender); recognize values of people; foster training and capacity building	(Norstrom et al., 2020;Schneider et al., 2019;Caniglia et al., 2021;Wuelser et al., 2021)

3	Co-dissemination and evaluation	Integrate and disseminate knowledge among research and societal groups in appropriate, relevant way; transparent discussion, critical reflection, and consequential actions	
3a	Two-dimensional integration	Review, discuss, and revise outcomes from societal and scientific perspective, e.g., prescriptive knowledge (recommendations about more desirable options)	(Lang et al., 2012;Caniglia et al., 2021;Mauser et al., 2013)
3b	Generate targeted products	Translate results for scientific progress (e.g., generalizability), and real-world problem solving (e.g., relevance, scaling up results, alliances, actions in specific contexts, products such as maps, manuals, information for policy makers); knowledge transfer by scientists and societal actors	(Lang et al., 2012;Jahn et al., 2012;Wuelser et al., 2021;Caniglia et al., 2021;Lemos and Morehouse, 2005;Mauser et al., 2013)
3c	Evaluate societal and scientific impact	Reference back to success factors (step 1b); impact can be defined in many ways, e.g., research quality, media attention, download rates, communities of practice, social networks, capacity building, education, concrete products, changing people’s lives; longer-term impacts are often not measurable	(Lang et al., 2012;Jahn et al., 2012;Norstrom et al., 2020;Schneider et al., 2019;Lemos and Morehouse, 2005)

2.2 Multi-Criteria Decision Analysis (MCDA)

180 2.2.1 MCDA in flood risk research

Methodological and epistemological perspectives in transdisciplinary research may still be debated (Jahn et al., 2012), but there needs to be consensus on methods used in a project, and the concept to integrate research (Lang et al., 2012). The FANFAR consortium agreed on Multi-Criteria Decision Analysis (MCDA) as organizing framework to integrate West African stakeholders in the transdisciplinary process and achieve the aim of producing the FANFAR system. MCDA is increasingly popular in hydrology, and specifically related to flood risks. A brief literature search revealed around 50 potentially relevant articles, but only few actually included stakeholders (Web of Science search 25.08.2021; keywords: “MCDA” AND “hydrolog*” AND/OR “flood*”). This corroborates results of two recent reviews (de Brito and Evers, 2016; Abdullah et al., 2021). Both confirm a significant growth in MCDA applications, especially for flood mitigation, while flood preparedness, response, or recovery phases were understudied. Moreover, uncertainty analysis and stakeholder participation were rarely applied, and require future exploration to increase the quality of decision making and success of implementation (de Brito and Evers, 2016). Our search indicates that most papers used MCDA as a technical method to (mathematically) integrate over various indicators, e.g., to support calibration of flood forecasting models (Pang et al., 2019). Recent methodologically interesting papers addressed MCDA coupled with e.g., artificial intelligence (Pham et al., 2021), machine learning (Nachappa et al., 2020), or portfolio decision analysis (Convertino et al., 2019). Combining GIS with MCDA is a trend in hydrology, as in other fields. Examples include flood risk assessment explicitly including uncertainty (Tang et al., 2018), a method to produce risk maps for a Swiss region (Ronco et al., 2015), and flood risk analyses and mappings for specific cases (e.g., Samanta et al., 2016).

This literature seems to lack integrating stakeholders in the decision analysis process, even in applied cases, a main conclusion of the review by de Brito and Evers (2016). These authors also propose a concept for inter- and transdisciplinary approaches to improve urban resilience in flood risk management using MCDA (Evers et al., 2018), and present a participatory case study in Brazil for flood vulnerability assessment (de Brito et al., 2018). Several studies state that MCDA results are highly susceptible to model assumptions, especially the weights assigned to objectives (de Brito and Evers, 2016). For instance, the sensitivity of MCDA results to weight variability was determined with global sensitivity analysis (Tang et al., 2018). In some of our screened papers, stakeholders actively participated, but again mainly to assign weights. However, most papers we checked seem technical, and stakeholder involvement was usually described in few sentences, presenting the weights in a table, without further elaboration of the process (e.g., Ronco et al., 2015). Concluding our short review, there seems to be a lack of research in hydrology that understands MCDA as a process, and that integrates stakeholders throughout this process.

2.2.2 Overview of transdisciplinary MCDA process

MCDA embraces various methodologies to support complex decisions (e.g., Belton and Stewart, 2002; de Brito and Evers, 2016). We chose MCDA, and specifically Multi-Attribute Value Theory (MAVT; Eisenführ et al., 2010; Keeney, 1982) for

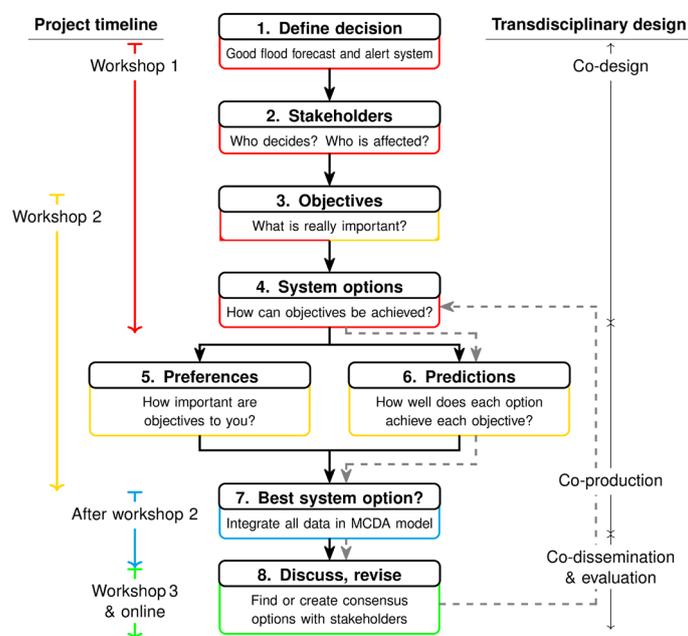

210 several reasons: (i) to develop a complex forecast system, many decisions had to be made. We needed to clarify, which hydrological models and data should be used to produce flood forecasts (e.g., type of meteorological forecast data, streamflow gauge observations), which flood hazard thresholds were appropriate, how to visualize model forecasts, or which distribution channels effectively reach people. MCDA is optimally suited to address such questions. (ii) Because the FANFAR system should be adapted to stakeholder needs, its development relied on close collaboration with nonacademic partners. MCDA is
215 a proven methodology that allows close interaction with stakeholders at various stages of decision making processes, offering a choice of methods for each stage. (iii) We used MAVT because it bases decisions on the objectives that are of fundamental importance to stakeholders. (iv) To evaluate options (i.e., system configurations), MCDA allows comparing and integrating different kinds of scientific and technical data from expert predictions (e.g., accuracy of forecasts, estimated costs of system development) with stakeholders' preferences. Disentangling facts from values can be very helpful, especially if
220 stakeholders have conflicting interests (Gregory et al., 2012a; Keeney, 1982). In most complex decisions, not all objectives can be fully achieved. MCDA explicitly asks stakeholders for the trade-offs they are willing to make. (v) MCDA allows including various types of uncertainty, e.g., of expert predictions with probability theory, or uncertain stakeholder preferences with sensitivity analyses (Reichert et al., 2015). (vi) MCDA is carried out stepwise, thus reducing complexity and increasing transparency. For these reasons, we used MCDA to identify a "Good flood forecast and alert system" for West Africa (see
225 practical research questions RQA, RQB; sect. 1.1). We present the MCDA methods such that they are easily accessible and adaptable to other transdisciplinary projects, e.g., in hydrology, and provide extensive details as blueprint in the Supplementary Information. Based on our experiences, we critically analyzed the MCDA process using the transdisciplinary framework (Table 1) to understand which elements were met by MCDA (RQC, RQD; presented in sects. 4.3 and 5).

A typical MCDA process starts with joint problem framing (Figure 1), as in the co-design step 1 of the transdisciplinary
230 framework (Table 1). Not part of MCDA *sensu stricto* were building the collaborative research team (step 1a), defining research questions and methodological framework (step 1b), and the boundary object, namely the FANFAR system (step 1c; Table 1). However, these steps were part of the FANFAR project with joint proposal writing and a kick-off meeting of European and West African consortium partners (section 2.2.3). As first step of the MCDA process, we undertook a stakeholder analysis (e.g., Grimble and Wellard, 1997; Lienert et al., 2013; Reed et al., 2009), which is often neglected in MCDA projects.
235 This was especially important, as European researchers worked in an unfamiliar African context. Main identified stakeholders that participated in the workshops were representatives from hydrological services, emergency management agencies, river basin organizations, and regional expert agencies. Together with these priority stakeholders, we then identified objectives ("What is of fundamental importance to be achieved by a FANFAR system?") and options ("Which FANFAR system configurations are potentially suitable to achieve objectives?"). To support these first MCDA steps, diverse "Problem Structuring Methods" (PSMs) are available in other fields of decision analysis (Rosenhead and Mingers, 2001). It is common to
240 combine MCDA with PSMs (reviewed by Marttunen et al., 2017). For a description of similar PSMs as used in FANFAR, we refer to an application in wastewater infrastructure planning (Lienert et al., 2015). The next steps 5–7 in MCDA (Figure

1), belong to the transdisciplinary co-production step 2 (Table 1). Hereby, research is conducted to produce new knowledge, in continuous exchange between scientists from different disciplines and stakeholders. A transdisciplinary process is often
 245 iterative (e.g., Jahn et al., 2012; Lang et al., 2012), captured in the FANFAR project with several cycles of workshops with decision makers, end users, and stakeholders (“stakeholders” hereafter) to test, discuss, and improve the FANFAR pre-operational system. In the co-dissemination and evaluation step 3, this new knowledge is critically reflected, integrated, and disseminated (Table 1), captured in step 8 of a typical MCDA process (Figure 1). After summarizing the workshops in Africa (sect. 2.2.3), we focus on the steps of the MCDA process (sects. 2.2.4 – 2.2.10).

250

Figure 1: Multi-Criteria Decision Analysis (MCDA) is carried out stepwise in the FANFAR project. Explanations see text.

2.2.3 Co-design workshops in West Africa

We carried out three workshops in West Africa, and a kick off meeting of the FANFAR consortium in Norrköping (Sweden, 17–18 January 2018). A fourth workshop was replaced by two half-day online workshops due to COVID-19 (20–21 January
 255 2021), and a final online workshop (01 June 2021). The workshops are documented in a detailed report (Lienert et al., 2020), and summary reports (FANFAR, 2021). At each workshop, West African representatives presented the flood situation in their country during rainy seasons and their experience with the FANFAR system. Each workshop hosted extensive technical sessions for experimentation with the latest FANFAR system, and structured technical feedback. Between workshops, the pre-operational system was adapted to meet requests as well as possible (Andersson et al., 2020a). We also conducted sessions
 260 with emergency managers, e.g., about their understanding of flood risk representation to improve visualizations of the FANFAR system (Kuller et al., 2020). In this paper, we focus only on interactions at the core of the MCDA process.

The first workshop in Niamey (Niger, 17–20 September 2018) hosted 47 participants from 21 countries, including consortium members from Europe and Africa, and representatives from hydrological service agencies and emergency management agencies on regional and national levels from 17 countries in West and Central Africa. Main aim was to initiate the co-design process. For MCDA, we carried out the problem structuring steps (Figure 1): a stakeholder analysis (sect. 2.2.4); different interactions to identify fundamentally important objectives of participants (i.e., what the system should achieve; sect. 2.2.5), and to identify system configurations that meet the objectives; sect. 2.2.6). The second workshop in Accra (Ghana, 9–12 April 2019) hosted 48 participants from 21 countries. For the MCDA, we consolidated the list of objectives, and elicited participants' preferences regarding achieving these objectives in small groups (sect. 2.2.8). Additionally, we collected preference data on the importance of objectives from each individual participant with questionnaires. This provided interesting insights into preference formation and changes over time (Kuller et al., in prep.). For the third workshop in Abuja (Nigeria, 10–14 February 2020), the number of participants increased to 58, including representatives from WMO (World Meteorological Organization; <https://public.wmo.int/>), ECOWAS (Economic Community of West African States; <https://www.ecowas.int/>), and from 16 West and Central African countries. We discussed main MCDA results. During one of the last online workshops, stakeholders completed a survey, providing some feedback for MCDA.

2.2.4 Stakeholder analysis

For the stakeholder analysis (Grimble and Wellard, 1997; Reed et al., 2009), we followed Lienert et al. (2013). The workshop participants filled in a pen and paper questionnaire in French or English, assisted by two experts. The survey was completed in 2.5 hours by 31 participants in 18 groups (for countries). After receiving information, the participants completed two tables, one for identifying key West African organizations involved in producing and operating flood forecast and early warning systems, and one for identifying downstream stakeholders (i.e., “Who might play a role because they use information from such systems in society?”). Each table contained eight tasks: (1) listing key organizations or stakeholders; (2) specifications (e.g., names); (3) their presumed main interests; (4) why they might use the FANFAR system; and (5) appropriate distribution channels. We used a 10 point Likert scale, asking participants to (6) rate the importance of considering each listed stakeholder or organization in the FANFAR co-design process; (7) the presumed influence (power) of each stakeholder for implementing the FANFAR system; and (8) how strongly each stakeholder or organization would be affected by the system (i.e., its level of performance). We cleaned the raw data and categorized stakeholders based on whether they are forecast/alert producers or users, their decisional level, sector, and perceived main interest. More details see Silva Pinto and Lienert (2018).

2.2.5 Generating objectives and attributes

Generating objectives is key to MCDA (Belton and Stewart, 2002; Eisenführ et al., 2010; Keeney, 1982), since this choice can alter results. Simply asking stakeholders is insufficient, and often too few (Bond et al., 2008; Haag et al., 2019c) or too many objectives are produced; we refer to the guidelines in Marttunen et al. (2019). Our stepwise procedure started at the FANFAR kick off meeting in Sweden and continued in the first two West African workshops (details see Lienert et al., 2020). In the first

workshop, we split participants into three groups. In the first, individuals used an interactive online survey to first brainstorm, then select objectives from a master list (Haag et al., 2019c). Individuals in the second group used the same procedure in a pen and paper survey assisted by a moderator. The third group used a means-ends network in a moderated group discussion to find consensus objectives (Eisenführ et al., 2010). Each participant (respectively group), ranked and rated objectives according to importance. Objectives were discussed in the plenary and the most important ones chosen by majority vote. Between workshops, we post processed objectives to avoid common mistakes such as double counting and overlaps, or including means objectives (Eisenführ et al., 2010). MCDA objectives are only useful if they discriminate options (system configurations in our case), and we dismissed those not fulfilling this requirement. In the second workshop, we presented a revised list of the 10 most important objectives, including a clear definition of the best and worst possible case for each (see description for attributes in sect. SI-2.4.1). For instance, for the objective “Several languages”, the FANFAR system being available in several languages is the best case, and only in English the worst. After discussion, the workshop participants agreed on the final list of objectives as basis for MCDA. To operationalize objectives, attributes (synonym indicators) are required (Eisenführ et al., 2010). These were developed by experts from the FANFAR consortium. In most cases, we constructed attributes from several sub-attributes (sect. 2.2.7). Sub-attributes or attributes were transformed to a value with help of marginal value functions (sect. 2.2.8). They were aggregated to a single total value with the MCDA model (sect. 2.2.9).

2.2.6 Generating system configurations

Different plausible FANFAR system configurations were generated in the first workshop, in three moderated group sessions. Two groups used the “Strategy Generation Table” (Gregory et al., 2012b; Howard, 1988), and one “Brainwriting 635” (Paulus and Yang, 2000) combined with “Cadavre Exquis” (write words on a paper, fold and give to next person). The Strategy Generation Table is a systematic procedure that allowed pre-structuring elements of the FANFAR system (e.g., observed variables, models for forecast production, language). The stakeholders chose elements forming suitable system configurations (“strategies”) with help of questions such as: “The most easy to use system”, or the “Most robust system working well given boundary conditions in West Africa (e.g., internet or power supply problems)”. Brainwriting 635 allowed for open, interactive brainstorming, using the same strategies as the other groups. All FANFAR system configurations were discussed in the plenary. As part of post processing, additional technically interesting system configurations were created by FANFAR consortium members. For readers unfamiliar with the methods, we provide details in the Supplementary Information (sect. SI-1.1).

2.2.7 Predicting performance of each system configuration

Part of the MCDA input data are scientific predictions (Figure 1), based on estimates or models of the level of achievement for each objective (Eisenführ et al., 2010). We used expert estimates (O’Hagan, 2019) by interviewing FANFAR consortium members in July–August 2019. First, experts developed attributes (sect. 2.2.5), in most cases constructed from sub-attributes. They estimated the outcome of each FANFAR system configuration for each (sub-) attribute, i.e., the likely level of each attribute (e.g., likely operation costs) and gave uncertainty ranges regarding their predictions. For constructed attributes, we

integrated the predictions of the sub-attributes into one final value using a weighted sum (weights defined by experts; sect. 2.2.8). We aggregated the uncertainty of each sub-attribute into a single uncertainty distribution with 1'000 Monte Carlo simulations. To characterize the resulting aggregated uncertainty, we used a normal distribution with mean (of Monte Carlo simulation), and standard deviation ($\frac{1}{4}$ of the 95 % confidence interval from simulation) as input in the MCDA (sect. 2.2.9).

330 Example: The objective “High accuracy of information” consists of three sub-attributes: KGE index for 1, 3, and 10 day forecasts (Kling-Gupta Efficiency; Gupta et al., 2009). The KGE is one possible accuracy index for hydrological model evaluation, e.g., to estimate the error of predicted vs. observed values. For each FANFAR system configuration and lead day, the expert estimated the expected KGE. The KGE index number was transformed to a value, ranging from 0 (worst) to 1 (best), with a nonlinear marginal value function, elicited from the expert. We aggregated the lead day values into a single value [0:1]
335 with a weighted sum, where the accuracy of the 1 day forecast received a weight of 0.5, the 3 day forecast of 0.4, and 10 day forecast of 0.1. Details for predicting system performance (expected achievement of stakeholder objectives) see sect. SI-2.4.

2.2.8 Eliciting stakeholder (or expert) preferences

Marginal value functions. Subjective preferences of stakeholders enter the MCDA model on equal footing to expert predictions (Figure 1). Preference elicitation is an important, sensitive step during which many biases can occur (Montibeller and von Winterfeldt, 2015). It is crucial to follow recommendations (Eisenführ et al., 2010). Marginal value functions convert the
340 attribute levels for each objective (e.g., KGE index for “High accuracy of information”) to a common scale ranging from 0 (worst possible achievement of this objective) to 1 (best achievement). This allows integrating different attributes with various units into one model, e.g., the KGE index with operation costs (€ / year), and development time (days). As default, a linear marginal value function can be used. However, nonlinear value functions usually better capture preferences. In FANFAR,
345 most attributes are relatively technical, requiring expert knowledge. We therefore elicited shapes of value functions from experts (sect. 2.2.7; details, including figures of value functions, see sect. SI-2.4.1). For each sub-attribute, we mostly created seven evenly spaced levels (worst, very bad, bad, neutral, good, very good, and best). Experts then assigned attribute numbers (e.g., KGE index for 3 day forecasts) to each level based on their experience. We transformed attribute levels to [0:1] values using linear interpolation between levels. As example, the KGE index ranges from minus infinity (worst case, value 0) to 1
350 (best case, value 1; Table SI-8). For attributes consisting of sub-attributes, we elicited a nonlinear marginal value function for each sub-attribute (Figure SI-5), allowing aggregation into one single value. Because we already used elicited nonlinear value functions to construct the composite attribute, we used a linear value function for these in the MCDA (sect. 2.2.9).

Weights. In the second FANFAR workshop, we elicited the weights by dividing participants into five groups according to language (French F, English E) and professional background (Emergency Managers EM, Hydrologists HY). The two French
355 speaking groups used the Swing method (Eisenführ et al., 2010): eight emergency managers (group ID: G1A_EM_F, where G1A = group), and 11 hydrologists (two sub-groups, G2A_HY_F, G2B_HY_F). The two English speaking groups used an adaptation of Simos’ revised card procedure (Figueira and Roy, 2002; Pictet and Bollinger, 2008), hereafter Simos card: 14

hydrologists (G3A_HY_E), and three emergency managers (G4A_EM_E). We separately elicited weights from three AGRHYMET experts with Simos card method (G5A_AGRHYMET). Stakeholders can be uncertain about their preferences, or groups may disagree. For Swing, we avoided forcing participants to reach group consensus and encouraged discussing diverging opinions. This resulted in a range of the stakeholders' weight preferences. We took the mean as main weight and considered strong deviations (difference in weights > 0.2 compared to mean) in later sensitivity analyses (sect. 2.2.10). For Simos' card procedure, two additional weight sets were used, resulting from eliciting a range for one variable. The moderator recorded important comments to inform the sensitivity analyses (Table SI-3). In the group of French speaking hydrologists, two diverging preference sets emerged from the start, which we analyzed separately (G2A, G2B). For interested readers, we give details of these standard MCDA weight elicitation procedures (sect. SI-1.2). To check for the validity of the additive aggregation model (sect. 2.2.9), we shortly discussed implications in the weight elicitation sessions using elicitation procedures from our earlier work (Haag et al., 2019a;Zheng et al., 2016).

2.2.9 MCDA model integrating predictions and preferences

The MCDA model integrates expert predictions with stakeholder preferences. An aggregation model is used to calculate the total value of each alternative (i.e., FANFAR system configuration; Eisenführ et al., 2010). A finite set of alternatives $A = \{a, b, \dots\}$ are evaluated regarding the predicted outcomes on every objective (respectively attribute). We denote the predicted outcomes (sect. 2.2.7) as $x_a = (x_{a,1}, \dots, x_{a,n})$, with $x_{a,i}$ being the level of an attribute i that measures a predicted consequence of system configuration a (or b, c, \dots). The total value $v(x_a)$ of system configuration a is calculated with a multi-attribute value function, $v(x_{a,1}, \dots, x_{a,n}, \theta)$. The resulting total value $v(x_a)$ of each system configuration lies between 0 (all objectives achieve only the worst level) and 1 (all objectives are on the best attribute level that can be achieved given the defined attribute ranges). A rational decision maker would choose the configuration with the highest value. Most commonly, an additive model based on marginal value functions is used, as in Eq. (1), but non-additive models as in Eq. (3) are also possible:

$$v(x_1, x_2, \dots, x_n, \theta) = \sum_{i=1}^n w_i \cdot v_i(x_i, \theta) \quad (\text{Eq. 1})$$

with parameters $\theta = (w_1, \dots, w_n, \theta)$, where w_i is the weight of attribute i , with $0 \leq w_i \leq 1$, and $\sum_{i=1}^n w_i = 1$, (Eq. 2)

and where $v_i(x_i, \theta)$ is the value for the predicted consequence x_i of attribute i of system configuration a . This value is inferred with help of the marginal value function (sect. 2.2.8).

While easy to understand, the additive model entails strong assumptions, e.g., that objectives are preferentially independent (Eisenführ et al., 2010). Increasing evidence indicates that many stakeholders do not agree with model implications (Haag et al., 2019a;Reichert et al., 2019;Zheng et al., 2016). Additive aggregation implies that good performance on one objective can fully compensate for poor performance on another. In the FANFAR weight elicitation sessions, we asked stakeholders, using

some examples, whether they agree with objectives being preferentially independent, and as consequence with the full compensatory effect. In all five groups this was not the case. We used a non-additive model with less strict requirements, the weighted power mean with an additional parameter γ that determines the degree of non-compensation, see Eq. (3):

$$390 \quad v(x_1, x_2, \dots, x_n, \theta) = (\sum_{i=1}^n w_i \cdot v_i(x_i, \theta)^\gamma)^{1/\gamma} \quad (\text{Eq. 3})$$

If $\gamma = 1$, we are back to the additive model in Eq. (1). We used a value for $\gamma = 0.2$, based on input from stakeholders (sect. 2.2.8), which is closer to a weighted geometric mean ($\gamma \rightarrow 0$). We shortly explain and visualize implications of the power mean in sect. SI-1.3. For further details we refer to (Haag et al., 2019b).

We calculated MCDA results in our new open source software “ValueDecisions” (Haag et al., *subm.*). ValueDecisions is based
395 on the software and programming language R (R Core Team, 2018), earlier R scripts developed in our group (e.g., Haag et al., 2019b), and R “utility” package (Reichert et al., 2013). R scripts were rendered as web application for ValueDecisions with the “shiny” package (Shiny, 2020) Additional analyses were implemented directly in R: aggregating uncertainty of sub-attributes, weight visualization, and statistical analysis of sensitivity analyses.

2.2.10 Uncertainty of predictions and preferences

400 **Uncertainty of predictions:** Probability theory is used in MAVT (Reichert et al., 2015). We defined uncertainty distributions from expert predictions for each attribute (sect. 2.2.7). We calculated aggregated values of each system configuration across all objectives (sect. 2.2.9), drawing randomly from the attributes’ uncertainty distributions in 1’000 Monte Carlo simulation runs. We analyzed rank frequencies: how many times in 1’000 runs each FANFAR system configuration achieved each rank.

Sensitivity analyses of aggregation model and stakeholder preferences: Local sensitivity analyses are commonly used to
405 check the sensitivity of MCDA results to diverging preferences (e.g., Eisenführ et al., 2010;Zheng et al., 2016;Haag et al., *subm.*). We checked the sensitivity of MCDA results to other aggregation models and changed weights. We used setting S0 as default, and compared results with those of a separate MCDA for each new setting with changed preference input parameters (settings are summarized in the Results, Table 3; details see sect. SI-1.4). For each setting, we compared mean ranks of FANFAR system configurations from 1’000 Monte Carlo simulation runs with those of the default MCDA (S0) using the nonpara-
410 metric Kendall’s τ correlation coefficient (Kendall, 1938) to measure rank reversals (as in Zheng et al., 2016). To test implications of the aggregation model (sect. 2.2.9), we recalculated the MCDA for other reasonable models (Haag et al., 2019a; settings S11–S14; Table 3). For weights, the weight of one objective is changed, while the ratios of all other weights are kept constant, and renormalized so that the sum of weights remains 1. For a thorough method explanation we refer to Eisenführ et al. (2010) and give some insight for readers not familiar with MCDA in sect. SI-1.4. Consistency checks during weight elicitation with the French speaking emergency managers (G1A) revealed an inconsistency, which resulted in strongly different
415 weights (Figure SI-3). We tested their effect on results in sensitivity analysis S21 (Table 3). For Swing weight elicitation, workshop participants stated ranges. We tested the sensitivity of results if the difference between the maximum or minimum

weight from the average exceeded $\Delta = 0.02$ (S22). Similarly, for Simos' card method, we tested alternative weight sets result-
ing from ranges (S23). It is common to test other interesting objectives by doubling the elicited weight. We did this for "Several
420 languages", because its importance might have been underestimated (S31).

Cost-benefit visualizations are an additional way to check robustness of results (e.g., Liu et al., 2019). This visual analysis is
based on the resulting MCDA, including stakeholders' preferences. We did this, using standard setting S0 without prediction
uncertainty (Table 3). For reasons of space, we refer to sect. SI-2.9.

2.2.11 Discuss results with stakeholders, feedback

425 We presented and discussed preliminary MCDA results with stakeholders in the third workshop. Because the fourth workshop
had to be carried out online, we were not able to thoroughly discuss results. However, we assessed stakeholder perceived
satisfaction with FANFAR system performance during the 2020 rainy season with an online survey to answer following ques-
tions for each objective: (a) How much does FANFAR currently fulfill this objective? (b) Would you use the FANFAR system
in the future if it remains as is? (c) What is the minimum acceptable to you? This means: below which level would you NOT
430 use the FANFAR system? (details see sect. SI-1.5). The survey was filled out by 12 participants, resulting for our 10 objectives
in $10 \times 12 = 120$ responses to each question.

3 Results

Here, we focus on the MCDA results, ordered as in the Methods section (sect. 2.2). This provides answers to the practical
research question (RQA). Based on these MCDA results, we address the other research questions in the Discussion.

435 3.1 Stakeholder analysis

Of 249 stakeholders listed by workshop participants, 68 distinct types remained after data cleaning (details see Silva Pinto and
Lienert, 2018). Stakeholders that were perceived to have high influence and also potentially being highly affected by the
FANFAR system were national entities for disaster management, water resources, and infrastructure, who were already well
represented in the co-design process (details Table SI-4). Several specific organizations were also perceived as highly im-
440 portant and affected, such as the "Autorité du Bassin de la Volta" (ABV), who participated in workshops, and AGRHYMET,
an organization representing 13 West African states and consortium member. Other important/affected parties were mainly
stakeholders receiving flood forecasts and alerts such as NGO's, electricity utilities, dam managers, and the agricultural sector.
The Red Cross and environmental protection agencies were perceived to have slightly lower importance/affectedness, among
others. Civil society (e.g., communities) would be strongly affected, but have limited decisional influence on developing the
445 FANFAR system. In contrast, the media, industry, and commerce were perceived to have more influence, but would not be
strongly affected. Such outlier stakeholders could potentially provide a different view to the FANFAR system.

3.2 Objectives and attributes

The objectives covered a broad range of issues that the stakeholders considered as fundamentally important in view of a *Good flood forecast and alert system* for West Africa (objectives, attributes, and system configurations are given in Italics hereafter; Figure 2). Several objectives concerned quality requirements for the forecasted flood information, grouped under *High information accuracy and clarity*, and aspects of *Good information access* by users such as accounting for language diversity. Aspects of *Low costs* and longer term *High sustainability* were also important, such as *Skillful human resources available* in West Africa, capable of maintaining, operating, and accessing the system. Each objective is characterized by an attribute, for operationalizing the achievement of objectives (Figure 2). Details of attribute calculations are given in sect. SI-2.4.

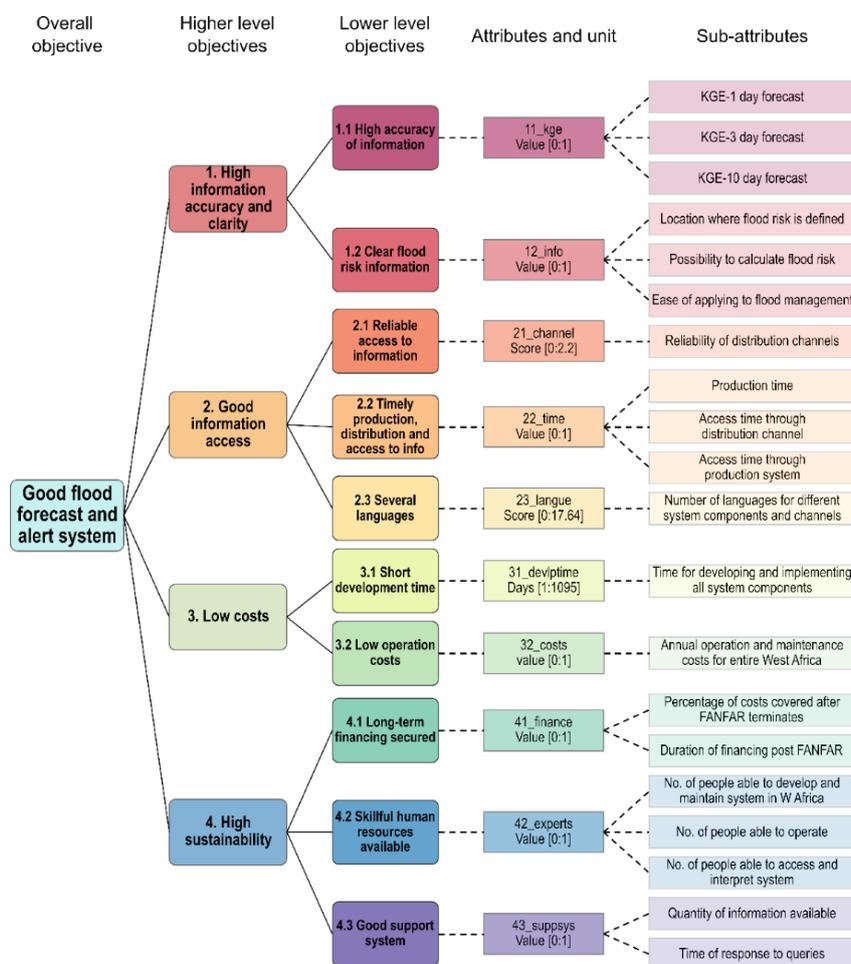

Figure 2. Objectives hierarchy. From left to right: overall objective, four higher level fundamental objectives, 10 lower level fundamental objectives and corresponding attributes, attributes' unit (usually a value) and range [square brackets], from worst (usually value = 0) to best (usually value = 1). Most attributes were constructed from several sub-attributes (far right).

3.3 FANFAR system configurations

460 Stakeholders generated six system configurations (b to g; Table 2) in workshop sessions. Experts of the FANFAR consortium developed five configurations (h to k) to cover important technical aspects such as using more refined hydrological models, e.g., redelineation and recalibration of the World Wide HYPE model to West Africa (Andersson et al., 2020b), and including earth observations from satellites. Configurations were constructed in separate sessions with experts from AGRHYMET for the forecast production system, and with stakeholders for the user interface IVP (Interactive Visualization Portal). They were
 465 combined to form plausible combinations of various FANFAR system elements (summary of important features in Table 2; for all system elements see Table SI-6 and Table SI-7). Configuration *a_Fast-dev* represents roughly the state of the first version of the FANFAR system, when stakeholders started experimentation and giving feedback in the first workshop.

470 **Table 2. Overview of 11 FANFAR system configurations. Selected main characteristics: recent hydrological observation data types (HydObs; WL: water level, Q: river discharge, EO: Earth Observations) & meteorological input/forcing data (MetF; HydroGFD; HydroGFD3 (Berg et al., 2020; improved version); HydroGFD-WA: HydroGFD2 adjusted by West African meteorological observations; Am: American meteorological forecasts (e.g., GFS); Ens: ECMWF ensemble meteorological forecasts); hydrological models (WWH: World-Wide HYPE); forecast output variables (Q: river discharge; WL: water level, P: precipitation; E: evaporation; SM: soil moisture, WQ: water quality); data download (Excel: table for selected station); distribution channels (Web: web visualization; H-TEP: login to H-TEP to download data; FTP: FANFAR and national FTP; API: Application Programming Interface; SoMed: Social Media e.g., WhatsApp; ConMed: conventional media e.g., radio, TV; Tradit: traditional word of mouth) & automatization (Automatic: automatic push of data to distribution channels; Manual: automatic processing with manual control of distribution by operator); flood hazard reference threshold types (RP Sim: return period based on simulations; RP Obs: return periods based on observations at gauged locations; HistY: selected historic year; Local: user defined thresholds for specific location); language of user interface (En: English; Fr: French; Pt: Portuguese; Ar: Arabic).**

ID	Configuration	Hydrological observations & meteorological forcing	Hydro-logical models	Forecast output variables	Data download	Distribution channels & automatization	Flood hazard thresholds	Language
a_Fast-dev	Least resources for development: no new features, status quo	HydObs: none; MetF: HydroGFD2	Niger HYPE	Q	None	Web; Automatic	RP Sim	En
b_Res-user	Least resources for users (e.g., skilled personnel, stable internet and power)	HydObs: in situ WL, Q; MetF: HydroGFD3	WWH	Q, WL, P, E, SM	Excel maps, graphs	Web, H-TEP, SMS, Email, SoMed, ConMed, Tradit; Manual	RP Sim, RP Obs, HistY, Local	En, Fr, Pt, Ar
c_Easy-use	Most easy to use for producing and interpreting forecasts and alerts	HydObs: EO WL; MetF: HydroGFD2	Niger HYPE	Q, WL, P, E	Excel graphs	Web, SMS, SoMed, ConMed, Tradit; Automatic	RP Sim, HistY	En, Fr, Pt

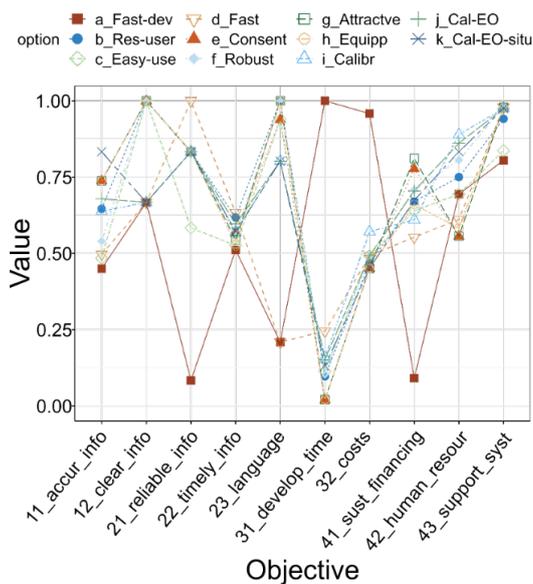

d_Fast	Fastest system for producing and distributing forecasts and alerts	HydObs: EO WL; MetF: HydroGFD2	Niger	Q	None	Web, SMS, Email, SoMed, ConMed, Tradit; Automatic	RP Sim	En
e_Con	Highest consensus: elements that West African stakeholders mostly agreed on	HydObs: in situ WL, Q, EO WL; MetF: HydroGFD-WA, Am, Ens	Niger	Q, WL, P, E, SM	Excel, maps, graphs	Web, H-TEP, SMS, Email, SoMed, ConMed, Tradit; Manual	RP Sim, HistY	En, Fr, Pt
f_Ro-	Most robust in West Africa: works despite problems in e.g., data collection	HydObs: EO WL; MetF: HydroGFD2	Niger	Q, WL, P, E, SM	Excel, maps, graphs	Web, H-TEP, SMS, Email, SoMed, ConMed, Tradit; Manual	RP Sim, RP Obs, HistY, Local	En, Fr, Pt, Ar
g_At-	Most attractive in West Africa: many desired features, similar to <i>h_Equipp</i> , but simpler distribution	HydObs: in situ WL, Q, EO WL; MetF: HydroGFD-WA, Am, Ens	Niger	Q, WL, P, E, SM, WQ	Excel, maps, graphs	Web, H-TEP, SMS, Email, SoMed, ConMed, Tradit; Manual	RP Sim, RP Obs, HistY, Local	En, Fr, Pt, Ar
h_Equ	Fully equipped: all system elements, except recalibrated HYPE models	HydObs: in situ WL, Q, EO WL; MetF: HydroGFD-WA, Am, Ens	Niger	Q, WL, P, E, SM, WQ	Excel, maps, graphs	Web, H-TEP, FTP, API, SMS, Email, SoMed, ConMed, Tradit; choice (Automatic or Manual)	RP Sim, RP Obs, HistY, Local	En, Fr, Pt, Ar
i_Cal-	Recalibrated HYPE models	HydObs: none; MetF: HydroGFD2	Recalibrated	Q, WL, P, E, SM	Excel, maps, graphs	Web, H-TEP, SMS, Email, SoMed, ConMed, Tradit; Manual	RP Sim	En, Fr, Pt
j_Cal-	Recalibrated HYPE models and EO data	HydObs: EO WL; MetF: HydroGFD2	Recalibrated	Q, WL, P, E, SM	Excel, maps, graphs	Web, H-TEP, SMS, Email, SoMed, ConMed, Tradit; Manual	RP Sim	En, Fr, Pt
k_Cal	Recalibrated HYPE models and EO data and in situ data	HydObs: in situ WL, Q, EO WL; MetF: HydroGFD2	Recalibrated	Q, WL, P, E, SM	Excel, maps, graphs	Web, H-TEP, SMS, Email, SoMed, ConMed, Tradit; Manual	RP Sim	En, Fr, Pt

480 3.4 Predicted performance of each system configuration

Based on expert predictions but excluding stakeholder preferences, no FANFAR system configuration achieved the best level of all objectives (Figure 3; details see sect. SI-2.4, raw input data for MCDA modelling Table SI-30). This illustrates the impossibility to design a perfect system, given the inherent trade-offs between achieving objectives. For instance, the status quo pre-operational system configuration *a_Fast-dev* achieved the highest values for objective *31_short development time*, and *32_costs*, but scored low on many others such as accurate, clear, reliable, and timely information. Configurations achieving high levels for objectives of *High information accuracy and clarity*, inevitably need longer *development time* and have *higher costs*. Therefore, it is not possible to clearly determine the “best” configuration based on only the predicted performance (Figure 3). We require input from stakeholders concerning which objectives are most important (sect. 3.5, sect. 3.6).

490 **Figure 3.** Predicted value (y-axis) of 11 FANFAR system configurations (a–k; symbols) for 10 objectives (x-axis), based on expert predictions, but not including stakeholder preferences. Value 1: this system configuration achieved the best level of this objective; 0: configuration achieved the worst level, given the ranges of the underlying attributes (i.e., it is a relative scaling from best to worst).

3.5 Stakeholder preferences

The elicited weights (w) for the four higher level objectives were similar for all groups (w = total bar length; Figure 4), except those of the French speaking emergency managers (G1A). These gave a high weight ($w = 0.25$) to 3. *Low costs*, which was least important for the others (0.1–0.12). G1A reasoned that all four higher level objectives are equally important in emergency situations with a connected chain of events. In contrast, the higher level objectives 1. *High information accuracy and clarity*, and 2. *Good information access* were generally regarded as most important by the other groups. There were some notable differences in importance of lower level objectives. Again, the French speaking emergency managers (G1A) were exceptional in assigning much lower weights to objectives they considered unimportant (objectives 23, 31, 41, and 43). They argued that

the goal in emergencies is to save lives, and FANFAR system development should focus on achieving fast access to flood alerts (*22_timely_info*; 0.21) and on personnel that can deal with this information (*42_human_resour*; 0.25). The weight sets in the other groups were overall more balanced (details see sect. SI-2.6). There were different levels of consensus about weights within a group, reflected in the length of the error bars (Figure 4).

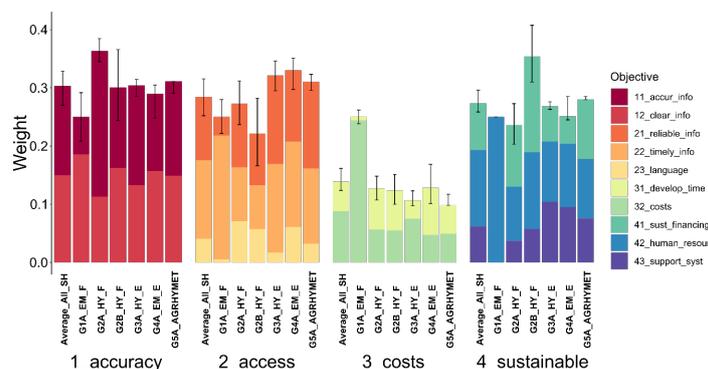

Figure 4. Weights (y-axis) assigned to higher level objectives (blocks, *1_accuracy*, *2_access*, etc.) colored by weights of lower level objectives (*11_accur_info*, *12_clear_info*, etc.), averaged over all six stakeholder groups (Average_All_SH), and for each group (G1A_EM_F, G2A_HY_F, etc.; x-axis). Error bars: uncertainty of elicited preference statements, i.e., the sum of uncertainties of all lower level objectives within the branch of the respective higher level objective. Per definition all weights of a group sum up to 1.

510 3.6 MCDA model results

No FANFAR system configuration clearly outperformed the others for all stakeholder groups in the standard MCDA (setting S0; Table 3) that did not consider uncertainty (Figure 5; details see Table SI-32; Table SI-33). The early stage configuration at the beginning of the project (*a_Fast-dev*) achieved lowest total values ($v < 0.46$) and the last rank for all stakeholder groups, except the French speaking emergency managers (group G1A, $v = 0.64$, rank 5). This can be attributed to the different weight preferences of G1A. All other configurations generally reached high values for all groups, with only small differences between groups. The total value ranged from $v = 0.55$ in the worst case (*d_Fast* for G2A) to 0.70 (*b_Res-user*, G3A). Indeed, this configuration *b_Res-user* seemed somewhat better than the others, achieving a high value ($v = 0.65$ – 0.70) for all groups, thus reaching the first rank for all, again with exception of group G1A, for which it still achieved the second rank. For better understanding [0,1] values can be interpreted as percentages, and *b_Res-user* was able to achieve 65–70 % of the ideal case over all objectives in all stakeholder groups. Configurations *f_Robust*, *i_Calibr*, *j_Cal-EO*, and *k_Cal-EO-situ* also performed well (0.63–0.70) for all groups, while *c_Easy-use*, and *d_Fast* achieved the lowest values (0.55–0.64).

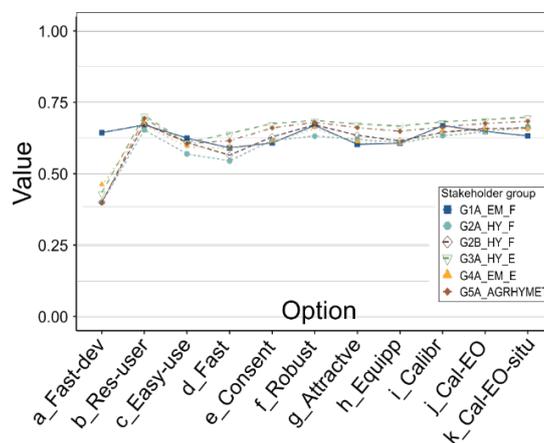

Figure 5. Total aggregated value (y-axis) of 11 FANFAR system configurations (x-axis) for six stakeholder groups (symbols), without uncertainty. Higher values indicate that they better achieves the objectives, given expert predictions and stakeholders’ preferences.

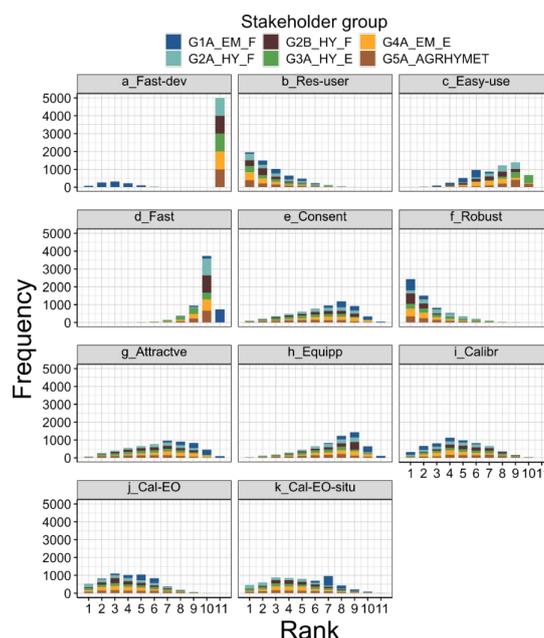

Figure 6. Ranks of 11 FANFAR system configurations including uncertainty of expert predictions. Frequency (y-axis): how often each configuration (blocks, *a_Fast-dev*, *b_Res-user*, etc.) achieves rank (1: best rank, 11: worst; x-axis) in each model run, for each stakeholder group (stacked bars). 1’000 Monte Carlo simulation runs draw from uncertainty distributions of attribute predictions.

Including uncertainty of the expert predictions in the MCDA with Monte Carlo simulation clarified results. The FANFAR system configurations *b_Res-user* and *f_Robust* performed well and achieved the highest ranks for all stakeholder groups in 1’000 simulation runs (Figure 6; details Table SI-34). The configurations *i_Calibr*, and *j_Cal-EO*, achieved good to medium ranks for most groups in most simulations. Poor performance was achieved by configurations *a_Fast-dev* (except group G1A), and *d_Fast*, which hit the last ranks in most simulation runs. The remaining configurations performed somewhere in between.

3.7 Sensitivity analyses of stakeholder preferences

535 The performance of FANFAR system configurations was not sensitive to most model parameter changes (Table 3). The least
 changes in rankings occurred between the standard MCDA (S0) and sensitivity analyses testing the extremes of the weight
 ranges elicited from stakeholders in the workshop (S22–S232; Table 3): Kendall’s τ rank correlations were high, ranging from
 0.86 to 1 (identical ranking of all configurations). Doubling the weight of *23_language* (S31) hardly impacted the rankings for
 any stakeholder group. Greater changes occurred using other aggregation models. The difference between our standard MCDA
 540 (S0) and changing aggregation models increased, the more the aggregation parameter γ increased from 0 (geometric mean;
 S12), over mixture models (S13, S14), to the additive model with $\gamma = 1$ (S11). Rank correlations were still relatively high
 between the additive model and our S0 standard model (0.53–0.86), and importantly, the rankings of the best-performing
 configurations, *b_Res-user* and *f_Robust* did not change (details sect. SI-2.8). For other configurations, including *i_Calibr*,
 there were some greater differences, depending on the group. The greatest changes occurred for an alternative weight set (S21)
 545 elicited in the group of French speaking emergency managers (G1A). Interestingly, this set moved the rankings and values of
 system configurations to those of all other groups, group G1A no longer being an outlier, and e.g., configuration *a_Fast-dev*
 clearly performing worst for all groups, also G1A (Figure SI-40). Cost-benefit visualizations confirmed that configurations
b_Res-user, *f_Robust*, and *i_Calibr* are suitable consensus configurations (provided in sect. SI-2.9 for reasons of space).

550 **Table 3. Results of local sensitivity analyses. Setting S0: default with elicited preferences of stakeholder groups and weighted power
 mean model, Eq. (3). Setting S11–S14: effect of other aggregation models (varying γ). S21–S22: uncertainty of Swing weights. S231–
 S232: uncertainty of Simos’ card method weights. S31: increase (possibly underestimated) weight. S11–S31: all other parameters as
 S0. Columns G1A to G5A: Kendall’s τ rank correlation coefficient between ranks of configurations in main MCDA (setting S0) and
 ranks resulting from MCDA using other settings (S11–S31) for stakeholder groups (e.g., group G1A). Column mean: correlation
 555 between S0 and average rank over all groups for which analysis was done. Note: S21 was only done for group G1A_E (i.e., mean =
 group correlation). Kendall’s τ 1: identical ranks; 0: no correlation; –1: inverse relationship; –: not applicable. Kendall’s τ from
 0.81–1.00: underlined, indicating very good agreement between changed setting and S0; τ from 0.61–0.80: dotted underlined.**

3.8 Stakeholders’ perceived satisfaction with the FANFAR system

Most respondents perceived the current performance as sufficient for all objectives, based on the direct question about future use of the current FANFAR system (b), and the inferred difference (c – a) between how much the current system fulfills the respective objective (a) and the minimum acceptable level (c). Across all objectives, 79 responses were positive, 16 negative, and 25 did not answer question b. For the most important objective, *11_accur_info*, all respondents would use the current system in future (Figure 7). However, four (of 12) respondents indicated that the system does not currently meet their minimum acceptable performance requirements. This result is representative of the results for all objectives (details see sect. SI-2.10).

565 **Figure 7. Stakeholder perceived satisfaction with the performance of the FANFAR system during the 2020 rainy season for objective**
***11_accur_info*. Questions: (a) How much does the FANFAR system currently fulfil this objective? (b) Would you use the system in**
the future if it remains as is? (c) What is the minimum acceptable to you? Colored dots represent unique respondents (N = 12).

4 Discussion

The discussion follows the research questions (sect. 1.3). RQA was confirmed: we found a robust FANFAR system configuration despite large uncertainty and different stakeholder preferences (sect. 4.1). We discuss our experience with MCDA related to uncertainty and eliciting stakeholder preferences in sect. 4.1.2. RQB was partly confirmed: early problem structuring focusing on objectives helped FANFAR system development (sect. 4.2). However, system developers needed MCDA weight elicitation asking for trade-offs to set priorities in the middle of the project, and full MCDA results to conclude that priorities were robust. In RQC we analyzed the MCDA process for guiding large transdisciplinary projects (sect. 4.3), following the

575 proposed framework (sect. 2.1.1; Table 1). For step 1, co-design and joint problem framing, various requirements were met by
the FANFAR project, but could not be attributed to MCDA (sect. 4.3.1). However, if MCDA is broadly understood as a
participative process that includes problem structuring, it can be very suitable for identifying stakeholders and guiding them
to focus on objectives for achieving a joint boundary object, the FANFAR system. For step 2, co-production of new knowledge,
MCDA is appropriate (sect. 4.3.2). Core strengths of MCDA are that it can integrate scientific knowledge from different
580 disciplines by providing a consistent framework and can handle uncertainty. MCDA invites stakeholders to clearly formulate
their preferences, and identifies consensus configurations. Step 3, co-disseminating knowledge and evaluation, can only partly
be achieved by MCDA (sect. 4.3.3). MCDA produces concrete, prescriptive knowledge: a suitable configuration of the FAN-
FAR system. However, MCDA is not appropriate for other aspects such as producing and implementing real-world solutions,
or impact evaluation. Main insights and recommendations are summarized in Table 4 and in the Conclusions (RQD, sect. 5).

585 4.1 Finding robust FANFAR system configurations (RQA)

4.1.1 Main MCDA results

As the most important practical result to RQA, we could identify three FANFAR system configurations that had a good overall
performance (Figure 5). This would be difficult to achieve without MCDA, given the uncertainty of expert estimates and the
model (Figure 6). Moreover, trade-offs between objectives had to be made (Figure 3), and stakeholders had different prefer-
590 ences concerning the importance of objectives (Figure 4). One well-performing configuration, *b_Res-user*, was created by
stakeholders in the first FANFAR workshop. They chose system components requiring the least resources for West Africa
such as skilled personnel, good internet connection, or stable power supply (Table 2). Similarly, configuration *f_Robust* was
created by stakeholders to reliably work under difficult West African conditions related to collecting in situ data and distrib-
uting information through a wide range of channels. The third configuration *i_Calibr* was created by FANFAR consortium
595 members focusing on using refined HYPE models (e.g., with adjusted delineation and parameter calibration; Andersson et al.,
2020b), but not including earth observation or in situ data (included in configuration *j* and *k*; Table 2). All three best configu-
rations achieved 63–70 % of all objectives in all stakeholder groups. We consider this a very good value, given the existing
trade-offs. These configurations also emerged as robust consensus from (i) including the uncertainty of expert predictions with
Monte Carlo simulation (Figure 6); (ii) sensitivity analyses of model assumptions and changing stakeholders' weight prefer-
600 ences (Table 3); and (iii) dominance checks in cost-benefit visualizations (sect. SI-2.9). Interestingly, none of these three
configurations incorporate more advanced system features. Hence, a flood forecast and alert system that meets the preferences
of the West African stakeholders primarily needs to work accurately and reliably under difficult conditions in West Africa.

4.1.2 Dealing with uncertainty of predictions, preferences, and model assumptions

Attributes operationalize objectives (Eisenführ et al., 2010). Seemingly trivial, this is often challenging. We illustrated this for
605 *11_kge*, constructed from the KGE index for 1, 3, and 10 day forecasts to measure achieving *1.1 High accuracy of information*

(sect. 2.2.7). The uncertainty of expert predictions was relatively large for some attributes (e.g., *11_kge*, *22_time*, or *42_experts*), but small to inexistent for others (*12_info*, *23_langue*; Figure SI-30). The resulting overall uncertainty affected the results less than might be expected (Figure SI-35).

The weights indicate that most groups preferred a system producing accurate, clear, and reliable information, reaching recipients well before floods (*11_accur_info*; *12_clear_info*; *21_reliable_info*; *22_timely_info*; Figure 4), and West African countries need the capability to handle this information (*42_human_resour*). We captured differences within groups with uncertainty ranges or separate preference sets (e.g., subgroups G1A, G2B; sect. SI-1.2.3; sect. SI-2.6). The French speaking emergency managers (G1A) had different preferences compared to all others. All groups regarded several languages as unimportant in weight elicitation, despite emphasizing in plenary discussions that language diversity is crucial. When asked to make trade-offs between accuracy and language, they were willing to give up the latter. They were also willing to trade-off higher operation and maintenance costs (except group G1A) and development time in return for receiving a functioning, precise system.

Including the uncertainty of expert estimates and stakeholder preferences in MCDA can blur results. For FANFAR, Multi-Attribute Value Theory and local sensitivity analyses (e.g., as Zheng et al., 2016) enabled identifying configurations suiting all stakeholder groups. Including the uncertainty of predictions helped to *better* distinguish between performances of configurations (Figure 6), compared to the standard analysis without uncertainty (Figure 5). Configurations *b_Res-user* and *f_Robust* consistently achieved the first ranks in 1'000 simulation runs, and e.g., *i_Calibr* good to medium ranks. However, some configurations such as *k_Cal-EO-situ*, ranked last in numerous runs (Figure 6), despite achieving good values when uncertainty was disregarded (0.63–0.70; Table SI-33). Ranking last in most runs, *a_Fast-* and *d_Fast_dev* would be an imprudent choice.

Local sensitivity analyses confirmed that configurations *b_Res-user*, *f_Robust*, and *i_Calibr* are robust choices. Changing stakeholder preferences hardly changed MCDA results compared to our standard model (S0; Table 3). Doubling the weight of *23_language* (S31) did not affect results in any group, thus avoiding costly translations as priority. Operation and maintenance costs would have been another candidate for doubling the weight, but was covered by the high weight of group G1A_EM_F. In this group, sensitivity analyses on weight ranges given by group participants with a different opinion (S21; Table 3) changed the results so that they aligned with results of the other stakeholder groups. This increases our confidence that the three proposed configurations are a good consensus. Moreover, the additive MCDA aggregation model (Eq. (1); sect. 2.2.9) impacted the rankings of the FANFAR system configurations (Table 3). As standard model, we assumed non-additive aggregation (Eq. 3), which is relatively close to a weighted geometric mean model, based on feedback in the weight elicitation sessions. After discussing examples, all groups stated that poor performance on an important objective should not be compensated by good performance on others, a main implication of additive aggregation. This confirms that the additive model can unintentionally violate stakeholder's preferences (e.g., Haag et al., 2019a; Reichert et al., 2019; Zheng et al., 2016). Thus, additive aggregation may not be the best model, despite its popularity in MCDA applications. For FANFAR, sensitivity analyses sufficed to conclude that additive aggregation has an effect, but does not alter rankings of the best configurations. We can thus safely conclude

that the three proposed FANFAR system configurations are suitable. We emphasize that the FANFAR system was continuously improved throughout the project, also after eliciting stakeholder preferences in the second workshop.

640 4.2 Early problem structuring focused FANFAR system development (RQB)

Early problem structuring steps helped focusing technical system development before MCDA results were available (RQB). This is important for agile development processes, since complex MCDA often takes considerable time to produce solid results. We emphasized objectives, rather than starting with FANFAR system configurations, motivated by “Value focused thinking” (Keeney, 1996). Asking: “What is important when designing a flood forecast and alert system for West Africa?” in the first
645 workshop allowed system developers to focus on priority objectives. Elicitation of stakeholder preferences in the second workshop further guided system design, e.g., that not all system components needed translation to several languages (sect. 4.1.2). Moreover, designing a flood forecast and alert system is complex (Andersson et al., 2020b;Arheimer et al., 2011;Emerton et al., 2016), with a risk of getting lost in stakeholder discussions about system elements. To avoid this, we included all stakeholder suggestions when creating system configurations. Hydrologists and ICT specialists then aimed at finding best solutions,
650 given the stakeholders’ priorities and experts’ predictions about system performance. To conclude, early problem structuring was useful, but later weight elicitation was needed to prioritize subsequent FANFAR system development. The MCDA results confirmed the robustness of mid-term priorities, which can be different in each case. We thus recommend doing the entire MCDA to test the sensitivity of results (sect. 4.1.2). The stepwise iterative approach employed here (beginning with key objectives, then focusing on system configurations), was very productive, and would likely be useful also in other projects.

655 4.3 Suitability of the MCDA process for guiding large transdisciplinary projects (RQC)

We discuss research question RQC following the framework for transdisciplinary research (Table 1). We critically evaluate a participatory MCDA process for guiding a large transdisciplinary research project. We focus on aspects that we consider important when carrying out MCDA in a hydrology context. Main points and recommendations are summarized in Table 4.

4.3.1 Evaluating the co-design step “joint problem framing”

660 The MCDA process does not fully meet all requirements of this step. In the FANFAR project, **building the collaborative research (or project) team** with consortium partners from Europe and West Africa was achieved (step 1a, Table 1), but not by MCDA. Two key West African stakeholders were consortium partners from the start: AGRHYMET (mandated by 13 West African states and ECOWAS to provide e.g., operational flood warnings), and NIHSA (Nigerian Hydrological Services Agency). This follows a decade of collaboration between SMHI and AGRHYMET. Building alliances with regional partners
665 is a transdisciplinary approach identified across projects, and may lead to partnerships in follow-up work (Wuelser et al., 2021). **Trust building** is crucial (e.g., Lemos and Morehouse, 2005), and AGRHYMET is clearly a **bridging organization or knowledge broker** (Norstrom et al., 2020;Wuelser et al., 2021) between research and implementation. The FANFAR project was co-led by West African partners and engaged stakeholders in workshops, meeting the principle of creating **knowledge**

670 *tailored to specific contexts* (Caniglia et al., 2021;Norstrom et al., 2020), but this is not due to MCDA. Similarly, MCDA was not responsible for *defining the research questions* (step 1b, Table 1), nor the *boundary object* (step 1c). FANFAR had a concrete boundary object, allowing stakeholders to commit (Jahn et al., 2012): producing an operational flood forecast and alert system. It was in the interest of scientists and stakeholders to achieve this goal, thus helping to overcome the problem of unbalanced ownership (Lang et al., 2012). The FANFAR consortium agreed to use MCDA as *integrative methodological framework* (1b) for achieving this objective. Literature emphasizes the importance of using methodologically consistent procedures for integrating across scientific disciplines (Lemos and Morehouse, 2005;Mauser et al., 2013;Lang et al., 2012). We regard MCDA as such a useful, stringent, and integrative methodology. Indeed, stakeholder related multi-criteria assessment (i.e., MCDA) was mentioned as one possible methodology to produce *transferable knowledge* (Wuelser et al., 2021).

Narrowing the perspective to the concrete project in West Africa with local stakeholders, an MCDA process that emphasizes early problem structuring (Marttunen et al., 2017;Rosenhead and Mingers, 2001) can be helpful. *Taking practitioners on board* from the beginning is crucial (Wuelser et al., 2021), and insufficient legitimacy or underrepresentation of actors is a challenge (Lang et al., 2012). To identify those that should be involved, stakeholder mapping or social network analysis are suitable (Norstrom et al., 2020;Lang et al., 2012). As first step of MCDA, we carried out a *stakeholder analysis* (step 1a, Table 1). However, in typical MCDA projects, stakeholder analysis was done in only 9% of 333 reviewed papers (Marttunen et al., 2017). We used relatively simple questionnaires (sect. 2.2.4) to discover who has influence or power, and who is affected by a good or malfunctioning flood forecast and alert system (Grimble and Wellard, 1997;Lienert et al., 2013;Reed et al., 2009). We identified 68 distinct stakeholder types (sect. 3.1). In the workshops, we included hydrology representatives from 17 countries, and key supranational organizations such as AGRHYMET who produce flood information (Table SI-4; details see Silva Pinto and Lienert, 2018). Main receivers of flood information also participated: emergency managers from every country. Thanks to their experience, we integrated the alert dissemination chain in FANFAR and elaborated elements of effective flood early warning systems (Kuller et al., 2021). We also identified missing parties, e.g., agriculture, industry (dam managers, electricity utilities), or humanitarian aid organizations, some of which provided informal feedback on the FANFAR system through social media. We did not invite them because more than 50 participants in workshops is ineffective. Indeed, *pluralistic co-production* while *keeping processes manageable* remains a challenge (Norstrom et al., 2020;Lang et al., 2012).

Problem structuring is decisive because MCDA results critically depend on objectives and options (i.e., system configurations Marttunen et al., 2017;Rosenhead and Mingers, 2001). These MCDA steps (Figure 1) were carried out in the first stakeholder workshop (sect. 2.2.5 and 2.2.6). At a specific level, the interactions helped define meaningful, *shared goals, and one measure of success* (e.g., Norstrom et al., 2020; step 1b, Table 1): to find a FANFAR system configuration that meets objectives that should be achieved by this system. Following “Value focused thinking” (Keeney, 1996), we first generated objectives in small groups using different methods (sect. 2.2.5) to ensure a broad diversity of objectives and avoid the common “group think bias” (Janis, 1972). We are confident that we captured the most important 10 objectives that cover fundamental aims of West African

stakeholders (Figure 2). Moreover, many environmental applications of MCDA use too many objectives (Marttunen et al., 2018). This is ineffective and burdens MCDA weight elicitation. We excluded some objectives in plenary discussions.

We could not assume that all participants had sufficient technical knowledge to *generate system configurations*, but aimed to avoid “myopic problem representation”, a bias to stick to what one knows (Montibeller and von Winterfeldt, 2015). We find the Strategy Generation Table (Gregory et al., 2012b; Howard, 1988) especially suitable. It pre-structures the process while allowing for creative stakeholder inputs. The *context-based principle* of co-production includes asking for constraining factors (Norstrom et al., 2020). When creating FANFAR system configurations, it became evident that e.g., frequent power cuts and slow internet in West Africa need consideration. Multi-Attribute Value Theory (Eisenführ et al., 2010) allows later including system configurations (Reichert et al., 2015). The FANFAR consortium created additional configurations to cover technical aspects, e.g., ensemble meteorological forecasts, redelineation and calibration of hydrological models, assimilation of EO water levels and in situ gauge observations from rivers (configurations *h* to *k*, Table 2; Table SI-6). The status quo system at project start, *a_Fast-dev*, was also created during post-processing to serve as benchmark. Indeed, it performed poorly for most groups (Figure 5). As summary, the three MCDA steps of stakeholder analysis, creating objectives and system configurations took up a large part of the first West African workshop. They were very helpful for stakeholders to exchange ideas, express their needs and wishes, and *develop a common understanding*, contributing to the co-design step 1 (Table 4).

Table 4. Summary of MCDA process using conceptual framework for transdisciplinary research (Table 1): (1) co-design, (2) co-production, and (3) co-dissemination of knowledge. Symbols: +++ strength of MCDA; ++ well possible with MCDA; + possible contribution by MCDA; 0 not achievable by MCDA; * remark. PSM: Problem Structuring Methods; VFT: Value Focused Thinking.

3c	Evaluate societal and scientific impact	+ 0 0	<ul style="list-style-type: none"> • MCDA usually does not evaluate societal and scientific impact (but is possible) • Mid-term impacts cannot be attributed to MCDA (e.g., uptake, societal effects) • MCDA cannot capture longer-term impacts, which are anyway difficult to measure

4.3.2 Evaluating the co-production step “integrated research to produce new knowledge”

720 Using consistent *integrative methods* (step 2a, Table 1) and *systematic procedures* for different bodies of knowledge (Lang et al., 2012; Mauser et al., 2013) is crucial, but seems less visible in literature (Wuelser et al., 2021). Recommendations include generating hazard maps, qualitative system analysis, scenario analysis, and sensitivity or multi-criteria assessments (i.e., MCDA). Applying procedures to identify stakeholders' positions and preferred configurations is beneficial because it involves

725 people in creating their future (Wuelser et al., 2021). MCDA clearly helped structuring the co-design process and integrating different types of knowledge: expert estimates of how well each FANFAR system configuration achieves each objective (sect. 3.4) and stakeholders' preferences (sect. 3.5). At each workshop, West African stakeholders experimented with the FANFAR system, tested it in rainy seasons, and provided feedback (see Wuelser et al., 2021), which cannot be attributed to MCDA.

730 Transdisciplinary projects rely on *interdisciplinary collaboration* (step 2b, Table 1; Jahn et al., 2012; Lemos and Morehouse, 2005). Methods must allow for consistent integration of scientific evidence from different disciplines to avoid “comparing apples with pears” (Mauser et al., 2013, p. 426). Integrating qualitative data for policy and decision making, and quantitative data required by models can be challenging (Lang et al., 2012). MCDA handles this by transforming attributes of different measurement units (including qualitative scales) to a common scale between 0 (objective not achieved) to 1 (objective fully achieved), using value functions (sect. 2.2.8). In FANFAR, experts from different disciplines provided these estimates: West African and European hydrologists, IT specialists, and decision analysts (sect. SI-2.4.1). MCDA integrates very specific data
735 (predictions about performance of system configurations). Other types of evidence also need integration in transdisciplinary projects, and other methods are available. This area merits future research, given the lack of emphasis in current literature.

“Questions of the *uncertainty of the results*” (Mauser et al., 2013; p. 428) were emphasized by earth systems scientists for global sustainability, but scarcely addressed by others (step 2c, Table 1). Our MCDA included the uncertainty of expert predictions by eliciting probability distributions for each attribute (sect. SI-2.4.1) and Monte Carlo simulation (sect. 2.2.10). Local
740 sensitivity analyses addressed uncertainty of the model and of stakeholder preferences (sect. 4.1.2; discussed in Reichert et al., 2015). Handling uncertainty in a conceptually valid way is essential for transdisciplinary research in earth systems science.

The importance of *integrating practice stakeholders in iterative processes* (step 2d, Table 1) was underlined by many (e.g., Lemos and Morehouse, 2005; Norstrom et al., 2020). Our iterative workshop series to test and improve the FANFAR system (sect. 4.1.2) cannot be attributed to MCDA. Practical MCDA projects often consist of three stakeholder interactions: a first
745 workshop for problem structuring, a second for preference elicitation, and a third for discussing results and revising options, i.e., system configurations (Figure 1). *Discontinuous participation* can be a challenge (Lang et al., 2012), also for FANFAR. The 3.5-year project involved representatives of at least two institutions from 17 African countries, regional stakeholders, and European partners, reflected in changing numbers and composition of participants (sect. 2.2.3). As Lang et al. (2012), we also encountered the opposite: increasing requests over time and the challenge of *keeping participant numbers manageable*. We
750 integrated new participants, e.g., by presenting the FANFAR system and MCDA objectives at each workshop. For MCDA, discontinuous participation was unproblematic, as new participants in the second workshop accepted the objectives (Figure 2) and system configurations (Table 2). This indicates that our participant sample was sufficiently large and diverse to cover the main aspects. Another challenge can be *vague results* when using methods such as sustainability visions, which may *conceal potential conflicts* (Lang et al., 2012). MCDA has the strength of providing clear results, even for uncertain data (sect. 4.1.2).

755 The *pluralistic principle aims at creating social learning across multiple axes* (step 2e, Table 1), and to build trust, e.g., by
recognizing values of people, providing trainings, and capacity building. Sustained interaction with stakeholders, jointly
searching for solutions, joint practices, and joint learning foster *trust, mutual understanding, and shared perspectives* (e.g.,
Lemos and Morehouse, 2005;Norstrom et al., 2020;Schneider et al., 2019), and “relationships of trust among participants make
760 *policy-making and implementation more likely to succeed*” (Lemos and Morehouse, 2005; p. 61). *Recognizing different ex-*
pertise, perspectives, values, and interests (e.g., Norstrom et al., 2020;Wuelser et al., 2021) does not require consensus to be
reached across conflicting interests, but implies collaboratively *engaging with conflicts* (Caniglia et al., 2021) to rationalize
contested situations (Schneider et al., 2019). A strength of MCDA is that opposing stakeholder interests are part of the meth-
odology, hereby often avoiding conflict about the choice of solutions (Arvai et al., 2001;Gregory et al., 2012a;Gregory et al.,
2012b;Marttunen and Hamalainen, 2008). In the weight elicitation sessions, we encouraged stakeholders to discuss diverging
765 preferences about the importance of objectives (sect. 2.2.8), and we recommend allowing for such uncertainty. It helps partic-
ipants *construct their own preferences* (Lichtenstein and Slovic, 2006), enables *learning* and *understanding alternative per-*
spectives, and can inform sensitivity analyses (sect. 3.7). In FANFAR, conflicting preferences did not change the ranking of
system configurations, and we identified consensus systems (sect. 4.1.2). In other cases, sensitivity analyses based on diverging
770 preferences can help construct better configurations. As interesting observation, in the first FANFAR workshop, participants
voted on objectives to include in the MCDA, which did not match an African perspective for all. Some participants criticized
the democratic approach, remarking e.g., that “the chief should decide”. “Assessing the [interactive] principle should also
focus on capturing learning, how the perceptions of actors change throughout the process, and the degree to which a *shared*
perspective emerges” (Norstrom et al., 2020; p. 188). Such research is rarely done in MCDA, but was attempted in FANFAR
and a Swiss project. We shortly elicited the importance of objectives at every workshop, hypothesizing that increased shared
775 understanding is mirrored by converging stakeholder preferences (Kuller et al., in prep.). Results were ambiguous, but we
found shared agreement of FANFAR stakeholders about the most important objectives. More research to better understand
individual cognitive and group decision making processes is needed (Kuller et al., in prep.).

Training and capacity building are components of the *pluralistic principle* (step 2e, Table 1). To foster joint understanding,
commitment, and trust, many of 31 analyzed transdisciplinary projects provided e.g., trainings, or attractive visualizations of
780 recent research (Schneider et al., 2019). Capacity building can be promoted by working in integrated ways of knowledge co-
production discussed above (Caniglia et al., 2021), or with capacity building courses (Wuelser et al., 2021). The FANFAR
project offered many training and capacity building opportunities, which cannot be attributed to MCDA.

4.3.3 Evaluating the co-dissemination and evaluation step “integrating and disseminating knowledge”

Two-dimensional integration (step 3a, Table 1) implies that project outcomes are *reviewed, discussed, and revised* from a
785 scientific and societal perspective (Mauser et al., 2013;Lang et al., 2012). Discussing *transformation knowledge* includes
measures, tools, or governance mechanisms to create change in the desirable direction (Schneider et al., 2019). It can include

prescriptive knowledge, recommending suitable options for realizing intentions (Caniglia et al., 2021). This is a strength of MCDA: in our case, we provided detailed information about good, robust FANFAR system configurations (sect. 4.1). Moreover, MCDA results are discussed with stakeholders and if needed, new consensus options are constructed (Figure 1). We were not able to carry out the fourth FANFAR workshop in West Africa due to the COVID-19 pandemic. We collected some feedback about how well the current FANFAR system meets the 10 objectives in an online survey. The stakeholders were quite satisfied with its performance during the 2020 rainy season (Figure 7), and are willing to use it in future. Although this does not meet requirements of extensive discussions, it was the best available approach. Understanding *governance mechanisms* is out of the scope of MCDA; in our case, ways to facilitate uptake of the FANFAR system across entire West Africa.

Target products (step 3b, Table 1) should address the original problem, be understandable, and accessible to users (Lemos and Morehouse, 2005; Schneider et al., 2019; Lang et al., 2012). Products include technical publications in appropriate language, data visualizations, and open access online databases (Schneider et al., 2019). In FANFAR, these products cannot be attributed to MCDA. Main product is the operational FANFAR flood forecast and alert system (including operational data collection, assimilation, hydrological modelling, interpretation, and distribution through web visualization and API), where MCDA only helped in the design. Additional products include a multilingual open access knowledge base (<https://fanfar.eu/support/>), the open source code (<https://github.com/hydrology-tep/fanfar-forecast>), and video tutorials (www.youtube.com, search: HYPE-web FANFAR). Assuring *consistent access, maintenance, updates, and improvements* after project termination is a challenge (Lemos and Morehouse, 2005). AGRHYMET has the authority to drive uptake of FANFAR in West Africa and already uses it beyond project activities, e.g., at PRESASS and PRESAGG forums (WMO, 2021) to support the ECOWAS flood management strategy, and in their MSc curriculum. Nevertheless, long term operationalization after EU financing is not guaranteed.

Products should contribute to scientific progress (Jahn et al., 2012), a major challenge being inadequate *generalization of case study solutions* (Lang et al., 2012). Products are often not reported in scholarly literature (Wuelser et al., 2021), the knowledge thus not advancing scientific progress, and not being adopted in societal praxis of similar projects. We aim to overcome this with this paper and other outputs (FANFAR, 2021). For MCDA, we document the process, and provide details in the Supplementary Information. We encourage hydrologists to use this material. We stress that it is not necessary to conduct a full MCDA in every case. Problem structuring (sect. 4.3.1) can create useful insights (sect. 4.2), and may be easier to apply.

The last step 3c (Table 1) is to *evaluate societal and scientific impact*. MCDA did not contribute to this, although project evaluation would be possible with MCDA. Short-term impacts can be visible in *increased citations or attention of nonacademic actors*, including download rates or media coverage (Norstrom et al., 2020; Schneider et al., 2019). This occurred; as example, the third FANFAR workshop in Nigeria featured on the national TV news. *Building social capacities and establishing stakeholder networks or communities of practice* can be very helpful (Lemos and Morehouse, 2005; Schneider et al., 2019). A FANFAR social media group among the West African stakeholders monitored the severe 2020 floods across the region, which in many places were successfully forecasted by the FANFAR system. Indicators of mid-term impacts relate to the *uptake of concrete products* and to societal effects of the transdisciplinary process such as *strategy implementation, or*

820 **amended legislation** (Jahn et al., 2012;Norstrom et al., 2020). **Long-term impacts** are very difficult to measure as they are
typically realized far beyond project termination (Norstrom et al., 2020;Schneider et al., 2019). Moreover, due to the complex-
ity of the problems addressed in transdisciplinary projects, it is difficult to establish causal relationships (Lang et al., 2012).
Whether the FANFAR flood forecast and alert system will be taken up broadly by West African stakeholders is uncertain.
However, it already had **societal impact**. As one example, the Nigeria Hydrological Services Agency, NIHSA reported that an
825 early warning received from the FANFAR system in September 2020 saved approximately 2500 lives. The warning helped
evacuating five communities before the flood destroyed more than 200 houses.

5 Conclusions

The MCDA process enabled identifying three good FANFAR system configuration (Research Question RCA; sect. 4.1), which
is important to West African stakeholders and those potentially affected by floods. These consensus configurations performed
830 well for all stakeholders, despite their diverging priorities. All stakeholder groups preferred a system producing accurate, clear,
and accessible flood risk information that reaches recipients well before floods. To achieve this, most groups would trade-off
higher operation and maintenance costs, development time, and several languages. The West African stakeholders preferred a
system that works reliably and accurately under difficult conditions in the region, but not necessarily including many advanced
features. MCDA demonstrated the robustness of these three configurations given different stakeholder perspectives, model
835 uncertainty, and uncertain expert predictions from different disciplines concerning FANFAR system performance (sect. 4.1.2).
The three FANFAR system configurations achieved 63–70 % of the entire set of objectives for all stakeholder groups. Inter-
estingly, the uncertainty analysis allowed to better distinguish between system configurations than standard MCDA without
uncertainty. We recommend using a participatory MCDA process to find suitable options in hydrology research. Emphasizing
objectives follows Value Focused Thinking (VFT), which helped avoiding potential conflicts about system configuration.
840 Important for practice, VFT was also beneficial to guide early technical FANFAR system development, before MCDA results
were available. However, eliciting the trade-offs that stakeholders were willing to make was necessary for later setting priori-
ties, and the robustness of results could not have been evaluated without the full MCDA (RQB; sect. 4.2).

From the perspective of sustainability science and transdisciplinary research, MCDA meets many, but not all requirements
(RCD; Table 4). The proposed evaluation framework based on literature proved very useful for our critical analysis of MCDA
845 (Table 1). We invite others to apply and evaluate it in their cases. Having practice-oriented hydrology research in mind, we
included elements underrepresented in literature, but crucial to earth systems sciences: uncertainty and integrating interdis-
ciplinary knowledge. We evaluated MCDA as a transdisciplinary process along the three framework steps (sect. 4.3). MCDA
can only partially contribute to co-design (step 1; Table 4; sect. 4.3.1), and is not appropriate for building the research team or
alliances with regional partners. However, if MCDA is understood as a process that includes problem structuring, it can support
850 joint problem framing. Stakeholder analysis is one method to identify those that should be involved; we recommend using a

relatively simple questionnaire. MCDA problem structuring also helps defining objectives shared by researchers and practitioners, and we recommend creativity techniques for engaging participants in developing options (i.e., system configurations). Joint MCDA problem structuring allowed bringing a relatively large number of stakeholders on board. The strength of a participatory MCDA process lies in its contribution to knowledge co-production (step 2; sect. 4.3.2). MCDA provides an integrative, consistent framework to produce transferable knowledge across different disciplines, using marginal value functions (sect. 2.2.8). Interdisciplinary integration was rarely emphasized in the reviewed literature, and could be a contribution of future research in the earth systems sciences. The same goes for explicit consideration of various types of uncertainty, which is a strength of MCDA (sect. 4.1.2). MCDA can also provide clear results and identify consensus system configurations by integrating conflicting stakeholder interests into the model (sect. 3.5). An MCDA process can enable social learning of participants, but does not foster training and capacity building. Finally, MCDA includes discussing results with stakeholders and constructing improved consensus configurations, but this focus is narrow (step 3, sect. 4.3.3). MCDA does not achieve important elements such as analyzing governance mechanisms, and developing or implementing actions and products. In FANFAR, we thus carried out complementary activities to be more comprehensive, beyond the limits of MCDA. We received feedback that stakeholders are willing to use the FANFAR system (Figure 7), and indications that it is already effective.

As many others, we believe that transdisciplinary research contributes to solving the complex problems our world is facing, and to advancing scientific progress. We hope that this paper documents and helps to better understand such a process in a complex setting: producing a good flood forecast and alert system for West Africa, together with many stakeholders. We contribute to literature by analyzing the strengths but also limits of a comprehensive MCDA process for such endeavors. We encourage our colleagues from the earth system sciences to engage in transdisciplinary research with stakeholders and society.

6 Data availability

The data will be available on the Eawag Research Data Institutional Collection (ERIC: <https://opendata.eawag.ch>) < DOI Link to be provided once paper is accepted >

7 Supplement link (< will be included by Copernicus, if applicable >)

In the Supplementary Information (SI), we provide ample material to guide readers unfamiliar with Multi-Criteria Decision Analysis (MCDA) through all steps. This includes a Methods section (generating system configurations, eliciting weights, MCDA model, sensitivity analyses, stakeholder feedback), and a Results section (stakeholder analysis, objectives and attributes, system configurations, predictions, marginal value functions, weights, MCDA results, and stakeholder feedback).

10 Special issue statement

This paper was prepared for the special issue: “Contributions of transdisciplinary approaches to hydrology and water resources management”; < The statement on a corresponding special issue will be included by Copernicus, if applicable >

11 Acknowledgements

This project received funding from the European Union’s Horizon 2020 research and innovation programme under grant agreement No. 780118: FANFAR (Reinforced cooperation to provide operational flood forecasting and alerts in West Africa (FANFAR, 2021). We thank Eawag, the Swiss Federal Institute of Aquatic Science and Technology, for providing additional funding to support the project during the COVID-19 prolongation period. We sincerely thank Abdou Ali, Addi Shuaib Olorunje, Aishat Ibrahim, Alice Aubert, Aytör Naranjo, Berit Arheimer, Bernard Minoungou, Bode Gbobaniyi, Cletus Musa, David Gustafsson, Emilie Breviere, Emmanuel Mathot, Fabrizio Pacini, Fridolin Haag, Kevin Schönholzer, Léonard Santos, Lorna Little, Melissande Machefer, Mohamed Hamatan, Philipp Beutler, Sara Schmid, Tharcisse Ndayizigiye, and Umar Magashi for their invaluable support when preparing the workshops, collecting data, and data analysis. We are truly grateful for the inspiring collaboration with the workshop participants, and we wish to sincerely thank them for their kindness and enthusiasm to work with us. We also thank three anonymous reviewers and the editors of this Special Issue for their helpful feedback.
