12 **Abstract:** In order to improve understanding of the characteristics of raindrop size
13 distribution (DSD) over complex mountainous terrain, the differences in DSD over the
14 southern slopes, northern slopes and interior of the Qilian Mountains were analyzed
15 using six months of observations. For all rainfall events, the number concentrations of
16 small and large raindrops in the interior and on the southern slopes were greater than
17 on the northern slopes, but midsize raindrops were less. The DSD spectrum of the
18 interior was more variable and differed significantly from that of the northern slopes.
19 The differences in the normalized intercept parameters of the DSD for stratiform and
20 convective rainfall were 8.3% and 10.4%, respectively, and those of the mass-weighted
21 diameters were 10.0% and 23.4%, respectively, while the standard deviations of DSD
22 parameters at interior sites were larger. The differences in the coefficient and exponent
23 of the Z-R relationship were 2.5% and 10.7%, respectively, with an increasing value of
24 the coefficient from the southern to the northern slopes for stratiform rainfall, but the
25 opposite for convective rainfall. In addition, the DSD characteristics and Z-R
26 relationships were more similar at the ipsilateral sites and had smaller differences
27 between the southern slopes and interior of the mountains.

31 1 Introduction

32 Raindrop size distribution (DSD), the number of raindrops per drop size per unit
33 volume, is an important parameter to statistically describe the microstructure of
34 precipitation (Bringi et al., 2003; Ma et al., 2019a). The measurement of DSD can
35 provide some fundamental information such as raindrop size (D), liquid water content
36 (W), rain rate (R), radar reflectivity factor (Z) and so on, which has an essential
37 contribution to improving quantitative precipitation estimation (QPE) using weather
38 radar and satellite observations (Adirosi et al., 2018; Jash et al., 2019). The
39 parameterization of DSD can obtain the distribution model parameters of DSD in
40 different rain types, which is significant in advancing microphysics parameterization in
41 numerical weather prediction (NWP) models (Wainwright et al., 2014; McFarquhar et
42 al., 2015; Zhao et al., 2019). In addition, understanding the DSD is crucial in many
43 applied fields concerning hydrology, agriculture, soil erosion and microwave
44 communication (Rincon et al., 2002; Smith et al., 2009; Angulo-Martínez et al., 2015;
45 Lim et al., 2015; Yang et al., 2016).

46 Numerous studies have been carried out on the statistical characteristics of DSD
47 in different regions (Campos et al., 2006; Seela et al., 2017; Dolan et al., 2018; Protat
48 et al., 2019; Loh et al., 2019; Jash et al., 2019). It has been shown that the number
49 concentration and size of raindrops increase with rain rate and so the DSD becomes
50 higher and wider. The characteristics in different rain types demonstrate that the mass-
51 weighted mean diameter (i.e., D_m) and normalized intercept parameter (i.e., N_w) of
52 convective rainfall are larger than those of stratiform rainfall. Furthermore, these
53 studies also reveal that there are more differences in the characteristics of DSD. Dolan
54 et al. (2018) divided global DSD characteristics into 6 types by using 12 datasets across
55 three latitudes and found that the centralized regions and DSD parameters of the 6 types
56 varied in location. The average number of raindrops in central Korea was usually
57 greater than that in the southeast under three rainfall systems, especially drops in the
58 0.31–0.81mm diameter range (Loh et al., 2019). According to DSD measurements in
59 the Tibetan Plateau region, eastern areas have a higher raindrop number concentration
60 in the diameter range of 0.437–1.625 mm and greater variation in diameters than in
61 central areas (Wang et al., 2020). Compared to eastern China and northern China, the
62 DSD in southern China shows a higher number concentration of relatively small-sized
63 drops (Zhang et al., 2019). Comparison of the Z - R relationship (defined as $Z=AR^b$)
64 indicates that the coefficient decreases with increasing R in the southern Tibetan Plateau,
65 which is opposite to the case in South China (Wu et al., 2017). For the DSD parameters
66 of stratiform and convective rainfall, there are various changes between the lower and
67 middle reaches of the Yangtze River (Fu et al., 2020).

68 As reported in the above studies, DSD characteristics vary significantly with
69 factors such as geographical location, climatic region and rain types. Pu et al. (2020)
70 analyzed the DSD characteristics of five sites in Nanjing city and found the N_w of DSD
71 to be largest at site near industrial areas, but the D_m of DSD was largest at sites near the
72 city's center. In other words, even at the urban scale, there are still differences in the
73 microphysical characteristics reflected by the DSD, which is due to the influence of the
74 surrounding environment. How, then, do the characteristics of DSD vary from location

75 to location over the complicated mountain terrain? Rao et al. (2006), by comparing the
76 DSD parameters at different altitudes, suggested that the obvious variation in DSD with
77 altitude is related to the processes of evaporation and breakup. Using aircraft
78 observations, Geoffroy et al. (2014) concluded that the total concentration of raindrops
79 decreased while the average drop size increased with decreasing altitude. But how large
80 might the differences in DSD be at different altitudes in mountainous regions? And how
81 significant might the effects be of these differences?

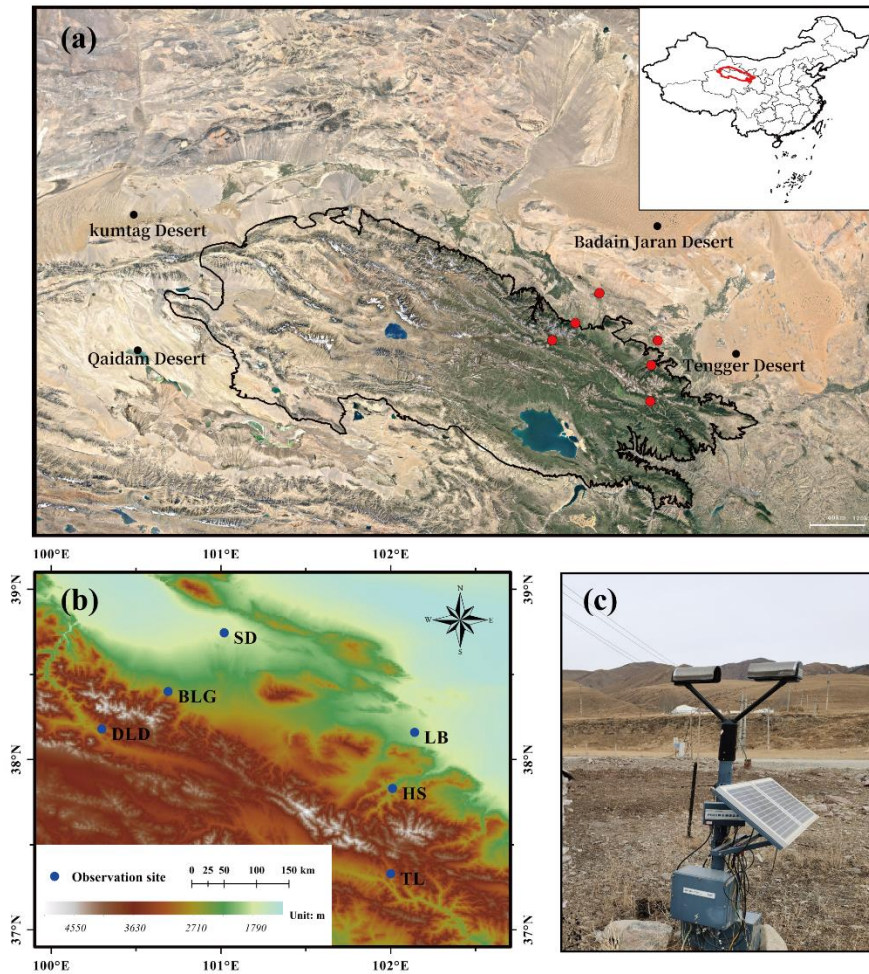

82 The Qilian Mountains, a series of marginal mountains in the northeastern part of
83 the Tibetan Plateau, are a vitally important ecological protection barrier in the northwest
84 arid areas of the region, that block the connection between deserts and wilderness
85 (Figure 1a). The mountains form several inland rivers that are important water sources
86 for the arid areas of the northwest and have therefore made a considerable contribution
87 to regional economic development (Gou et al., 2005; Tian et al., 2014; Qin et al., 2016).
88 In this study, we chose the Qilian Mountains as the research object and selected six sites
89 with different backgrounds representing the southern slopes, northern slopes and
90 interior of the mountains. To thoroughly investigate the discrepancies in this complex
91 mountain terrain, the DSD characteristics and *Z-R* relationships were comprehensively
92 analyzed according to different rain types based on continuous disdrometer
93 observations in the rainy season. The primary goal was to obtain a deeper understanding
94 and characteristic differences of DSD over the Qilian Mountains and improve the
95 accuracy of QPE, which could then be used as a research foundation for developing
96 cloud water resources in mountainous areas.

97 **2 Data and method**

98 **2.1 Sites and instruments**

99 The eastern and middle sections of the Qilian Mountains were chosen as the main
100 study area, taking into account that several important inland rivers originate from these
101 areas (Li et al., 2019). Six disdrometers were deployed on the southern slopes, northern
102 slopes and interior (close to the ridge) of the Qilian Mountains, with three sites in the
103 eastern section [called Taola (TL), Huangchengshuiguan (HS) and Liuba (LB), from
104 south to north] and another three sites in the middle section [called Daladong (DLD),
105 Boligou (BLG) and Shandan (SD), from south to north]. The background of the Qilian
106 Mountains is shown on the satellite map in Figure 1a, and the six sites are marked on
107 the topographical map, also in Figure 1b. The distances between the six sites are listed
108 in Table 1. The sites in the south, north and interior are basically parallel to the
109 orientation of the mountains, and the sections formed by the sites in the east and interior
110 are basically perpendicular to it. On the basis of an historical weather review and rain
111 gauge observations, the rainy season at the six sites is concentrated in May to October,
112 with more precipitation in July, August and September.

 119 pairs of sites.

Six sites	LB	HS	TL	SD	BLG	DLD
LB (38.16°N, 102.14°E, 1926m)	-	39.6	94.3	116.0	129.6	161.1
HS (37.83°N, 102.01°E, 2342m)	-	-	55.6	135.1	132.8	154.9
TL (37.33°N, 102.00°E, 2910m)	-	-	-	182.4	167.3	177.0
SD (38.80°N, 101.08°E, 1765m)	-	-	-	-	54.2	96.8
BLG (38.4°N, 100.69°E, 2455m)	-	-	-	-	-	43.3
DLD (38.18°N, 100.3°E, 2957m)	-	-	-	-	-	-

120 This study used an optical, laser-based device to measure the DSD, called a DSG4
 121 disdrometer (Figure 1c), which meets the Functional Specification Requirements for
 122 Disdrometer issued by the China Meteorological Administration. This disdrometer has
 123 an HSC-OTT Parsivel2 sensor as the observation part, manufactured by OTT
 124 Messtechnik (Germany) and Huatron (China). When raindrops pass through the
 125 horizontal flat laser beam generated by the transmitting part of the instrument, it causes

126 signal attenuation in the laser observation area. The raindrop size is determined by the
 127 degree of signal attenuation and the falling speed is recorded by the transit time. The
 128 sampling time is 60s and the velocity and drop sizes are divided into 32 non-equally
 129 spaced bins, varying from 0.05 to 20.8 m s⁻¹ for velocity and 0.062 to 24.5 mm for drop
 130 diameter.

131 2.2 Quality control of the data

132 It was necessary to quality control the data because of potential instrument error.
 133 Every minute of DSD data collected by the six DSG4 disdrometers from May to
 134 October 2020 was carefully processed. Specifically, the following criteria were
 135 employed in choosing data for analysis(Jaffrain et al., 2011; Guyot et al., 2019; Pu et
 136 al., 2020): (1) the first two size bins were ignored because of low signal-to-noise ratio;
 137 (2) samples with 1-min total of raindrop number less than 10, or a rain rate at the
 138 moment of discontinuous observation less than 0.1 mmh⁻¹ were regarded as noise; (3)
 139 raindrops with diameters more than 8 mm were eliminated; (4) raindrops with a falling
 140 terminal velocity $V(D_i)$ that deviated from the empirical terminal velocity $V_{emp}(D_i)$ by
 141 more than 40% were removed (Kruger and Krajewski, 2002); and (5) samples with less
 142 than five bins after the correction of falling terminal velocity were deleted because their
 143 DSDs could not be determined with too few bins. The fourth criterion can be expressed
 144 by the formula:

$$145 \quad |V(D_i) - V_{emp}(D_i)| < 0.4V_{emp}(D_i) \quad (1)$$

146 where $V_{emp}(D_i) = 9.65 - 10.3\exp(-0.6D_i)$ (D_i is the mean volume-equivalent
 147 diameter of the i th size category), as derived from the formula given in Atlas et al.
 148 (1973).

149 After data quality control, the sample statistics of key steps are shown in Table 2.
 150 The number of 1-min DSD spectra selected from the six sites (LB, HS, TL, SD, BLG,
 151 DLD) after data quality control covering the rainy season (May–October) in the Qilian
 152 Mountains region in 2020 were 11103, 17619, 14814, 10736, 18861 and 13230,
 153 respectively, which accounted for 87.9%, 85.8%, 84.5%, 91.2%, 80.6% and 86.5% of
 154 the total number of samples.

155 Table 2. Sample statistics of data quality control at six sites

Samples	LB	HS	TL	SD	BLG	DLD
Total minutes (min)	12625	20536	17526	11770	23401	15289
Total minutes without noise (min)	12602	20509	17494	11756	23371	15267
After quality control (min)	11103	17619	14814	10736	18861	13230
Available rain minutes (%)	87.9%	85.8%	84.5%	91.2%	80.6%	86.5%

156

157 2.3 Integral parameters of rainfall

158 The basic observations obtained by the disdrometer were the counts of raindrops
 159 at each diameter and velocity. Also, the diameters given by the disdrometers were the
 160 mid value of two adjacent bins, which we take as the corresponding endpoint bin values.
 161 The velocities were the weighted average velocity class over the corresponding

162 disdrometer. The raindrop number concentration $N(D_i)$ ($\text{m}^{-3} \text{mm}^{-1}$) in the i th size bin
 163 per unit volume per unit size interval for diameter was calculated by the following
 164 equation:

$$165 \quad N(D_i) = \sum_{i,j=1}^{32} \frac{n_{i,j}}{A \cdot \Delta t \cdot V_j \cdot \Delta D_i} \quad (2)$$

166 where $n_{i,j}$ denotes the counts of raindrops measured by the disdrometer within size bin
 167 i and velocity bin j during the sampling time Δt ; A and Δt are the sampling area (0.0054
 168 m^2) and sampling time (60 s), respectively; V_j (m s^{-1}) is the mid-value falling speed for
 169 velocity bin j ; and ΔD_i is the diameter spread for the i th diameter bin.

170 Some integral rainfall parameters, such as the total number concentration N_t (m^{-3}),
 171 rain rate R (mm h^{-1}), radar reflectivity factor Z ($\text{mm}^6 \text{m}^{-3}$) and liquid water content W
 172 (g cm^{-3}), can be derived by the following equations:

$$173 \quad N_t = \sum_{i=1}^{32} N(D_i) \Delta D \quad (3)$$

$$174 \quad R = \frac{6\pi}{10^4 \rho_w} \sum_{i=1}^{32} V(D_i) D_i^3 N(D_i) \Delta D_j \quad (4)$$

$$175 \quad Z = \sum_{i=1}^{32} N(D_i) D_i^6 \Delta D_i \quad (5)$$

$$176 \quad W = \frac{\pi \rho_w}{6 \times 10^3} \sum_{i=1}^{32} D_i^3 N(D_i) \Delta D_i \quad (6)$$

177 where ρ_w is the water density (1.0 gcm^{-3}); and $V(D_i)$ is the falling speed from the
 178 disdrometer. In this study, when calculating the rain rate we use $V_{emp}(D_i)$ to replace $V(D_i)$
 179 because of measurement error, particularly at larger bins and faster falling speeds.

180 The characteristics of DSD can be described by a three-parameter gamma
 181 distribution in the form introduced by Ulbrich (1983). Also, it has better fitting
 182 capability than the M-P distribution on the broader variation of DSD fluctuations,
 183 including the middle rain drops, especially on small and large rain scales. The three-
 184 parameter gamma distribution can be expressed by the following formula:

$$185 \quad N(D) = N_0 D^\mu \exp(-\Lambda D) \quad (7)$$

186 where $N(D)$ is the raindrop number concentration; D is the raindrop bins with unit mm;
 187 and N_0 , μ and Λ are the intercept, shape and slope parameter from the three parameters
 188 of the gamma model, which can be derived from gamma moments or the least-squares
 189 method, respectively. When $\mu=0$, it degenerates into the M-P DSD model.

190 Although, the gamma distribution is commonly accepted, the normalized gamma
 191 distribution has also been widely adopted with its independent parameters and clear
 192 physical meaning as follows (Dolan et al., 2018; Ma et al., 2019):

$$193 \quad N(D) = \frac{3}{128} N_w \left[\frac{(4 + \mu)^{(4+\mu)}}{\Gamma(4 + \mu)} \right] \left(\frac{D}{D_m} \right)^\mu \exp \left(\frac{-(4 + \mu)D}{D_m} \right) \quad (8)$$

194 where μ is the shape parameter, which is in dimensionless; D_m (mm) is the mass-
 195 weighted mean diameter, and N_w ($\text{m}^{-3} \text{mm}^{-1}$) is the normalized intercept parameter
 196 computed from D_m . The form is as follows:

$$197 \quad D_m = \frac{\sum_{i=1}^{32} N(D_i) D_i^4 \Delta D_i}{\sum_{i=1}^{32} N(D_i) D_i^3 \Delta D_i} \quad (9)$$

$$198 \quad N_w = \frac{4^4}{\pi \rho_w} \left(\frac{10^3 W}{D_m^4} \right) \quad (10)$$

199 3 DSD parameter characteristics

200 3.1 Characteristics of DSD

201 Figure 2a shows the mean DSDs for the six sites during the rainy season in the
 202 Qilian Mountains. The maximum concentration of raindrops was around 0.562 mm in
 203 diameter and the maximum number concentration values of sites were order as follows:
 204 BLG>TL>DLD>HS>SD>LB. As the diameter increased, the number concentration
 205 decreased and the concentration values followed the order
 206 LB>SD>DLD>TL>BLG>HS at around 2 mm in diameter. When the diameter was
 207 larger than 4 mm, the concentration at TL, BLG and HS was relatively high. In this
 208 study, the data were roughly divided into small raindrops (less than 1 mm in diameter),
 209 midsize raindrops (1–3 mm) and large raindrops (greater than 3 mm) to easily describe
 210 the difference in DSDs (Ma et al., 2019b; Pu et al., 2020). To highlight the DSD
 211 differences caused by the background environment, Figure 2b shows the mean DSDs
 212 normalized by the N_w and D_m results for the sites. Compared with Figure 2a, the
 213 raindrop characteristics were more consistent across sizes, while the differences
 214 between the sites were more pronounced, especially in the midsize and large raindrops,
 215 which truly reflected the DSD differences caused by the location. Combining the
 216 characteristics of the geographical environment of the six sites, we can analyze some
 217 differences in DSD characteristics in the Qilian Mountains. For small raindrops, the
 218 number concentrations at interior and southern-slope sites were greater than at northern-
 219 slope sites; for midsize raindrops, the number concentrations decreased sequentially at
 220 the northern-slope, southern-slope and interior sites; and for large raindrops, the number
 221 concentrations at the interior sites were larger. In addition, the number concentrations
 222 of raindrops in the middle section of this the mountainous area were slightly greater
 223 than those in the eastern section.

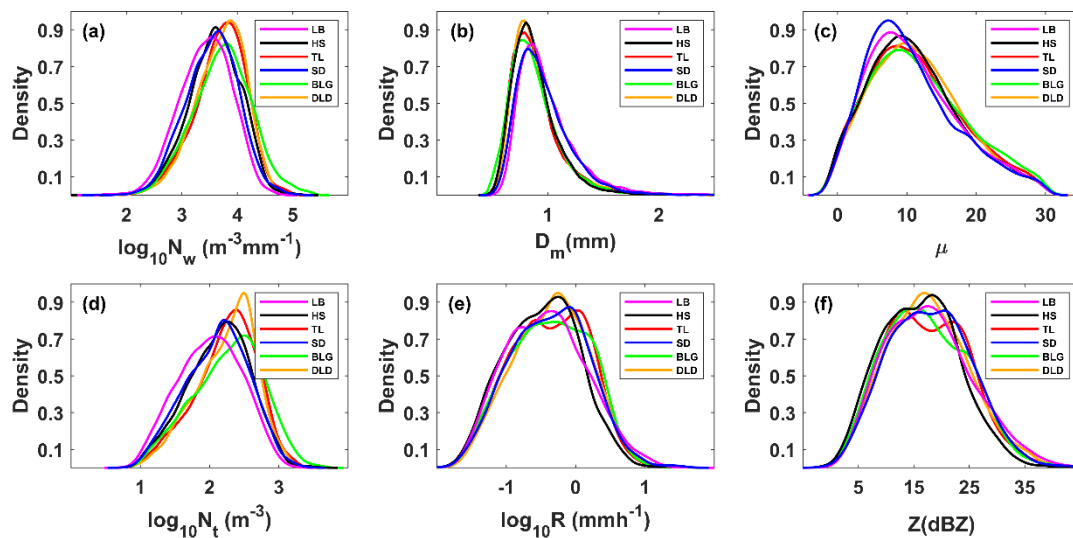

224

225 Figure 2. The (a) mean and (b) normalized mean DSDs at six sites in the Qilian
 226 Mountains region in the rainy season

227 3.2 Distribution of DSD parameters

228 In order to study the differences in DSDs, we selected six integral rainfall
 229 parameters for discussion—namely, the normalized intercept parameter (N_w), mass-
 230 weighted mean diameter (D_m), shape parameter (μ), total number concentration (N_t),
 231 rain rate (R) and radar reflectivity factor (Z). Figure 3 and Table 3 show the distributions
 232 and statistics of these six DSD parameters (the distribution of each was normalized
 233 using the uniform method). On average, D_m was more concentrated on smaller values
 234 at HS and BLG, which showed smaller mean values than TL and DLD but significantly
 235 more values greater than 1 mm at LB and SD; $\log_{10}N_w$ was more centralized on larger
 236 values at TL and DLD, with relatively smaller values at LB and SD; and the distribution
 237 patterns for μ and $\log_{10}N_t$ were similar to those for $\log_{10}N_w$. The density curves of R and
 238 Z were similar, but there were differences among the six sites, which are analyzed in
 239 detail later in the paper. It is noteworthy that the frequency of samples with R around
 240 $0.6\text{--}1.0\text{ mm h}^{-1}$ was highest, and samples with R less than 1 mm h^{-1} accounted for more
 241 than half of the total rainfall.

242
 243 Figure 3. Probability density distribution of integral DSD parameters at six sites (LB,
 244 HS, TL, SD, BLG, DLD): (a) normalized intercept parameter $\log_{10}N_w$ ($\text{m}^{-3}\text{mm}^{-1}$); (b)
 245 mass-weighted mean diameter D_m (mm); (c) shape parameter μ ; (d) total number
 246 concentration $\log_{10}N_t$ (m^{-3}); (e) rain rate R (mm h^{-1}); (f) radar reflectivity factor Z (dBZ)

249 Note: ME is mean; SD is standard deviation; SK is skewness.

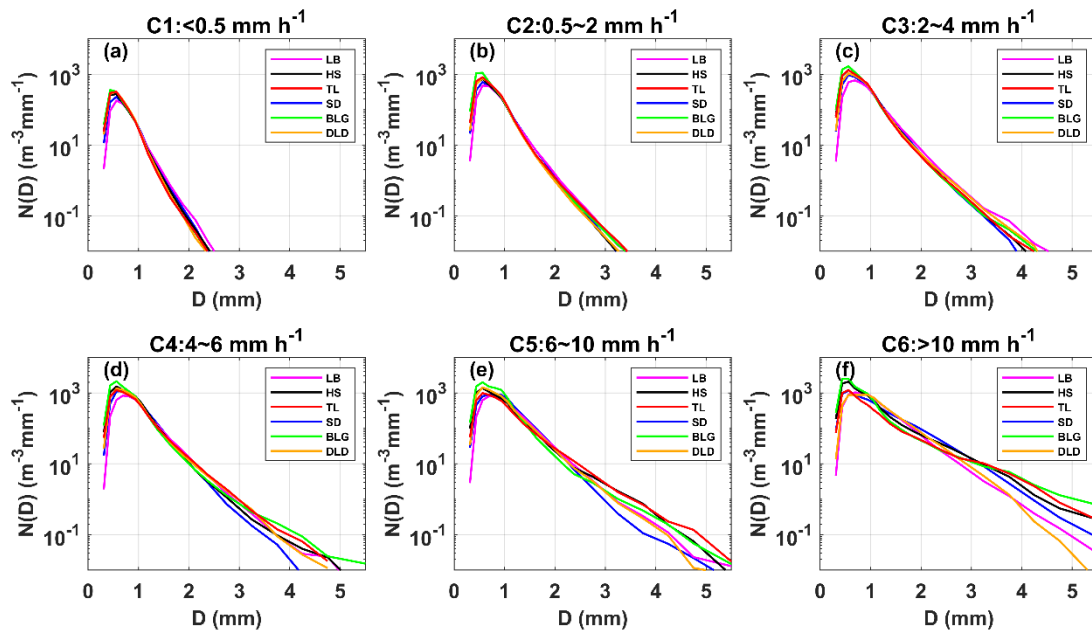

250 3.3 DSD characteristics in different rain rate classes

251 To further understand the characteristics of DSDs at the six sites, the samples were
252 divided into six classes according to the associated rain rates (R): C1, $R < 0.5$; C2,
253 $0.5 \leq R < 2$; C3, $2 \leq R < 4$; C4, $4 \leq R < 6$; C5, $6 \leq R < 10$; C6, $R \geq 10$ mm h⁻¹. This classification
254 was based on two considerations: firstly, the number of observation samples in different
255 rainfall rates roughly conformed to a normal distribution; and secondly, the mean
256 maximum diameter interval of different rainfall rates gradually increased (Li et al.,
257 2019). Of course, other classification studies were referenced and the fact that the rain
258 rate in this area is smaller than that in southern China was taken into account (Ma et al.,
259 2019b; Zeng et al., 2021). Figure 4 shows the mean DSDs at each rainfall rate class for
260 the six sites. Table 4 lists the number of samples and statistical values of the DSD
261 parameters for the six classes. Clearly, as the rainfall rate increased, the number
262 concentration of almost all raindrop sizes and the width of DSD shapes increased, and
263 thus the tail of the DSD shape moved gradually towards a larger diameter, similar to
264 previous findings, such as those of Ma et al. (2019b) and Pu et al. (2020). Taking a
265 number concentration of 0.01 m⁻³mm⁻¹, the mean maximum diameter of DSD in each
266 class was ordered as follows: 2.3–2.5, 3.2–3.4, 3.9–4.5, 4.3–5.0, 5.0–5.6 and 6.0–7.0
267 mm (the sixth-class diameter range is not fully shown in the figure). In class C1, the
268 number concentrations were relatively similar at different sites; starting from class C2,
269 the differences in number concentration increased when the diameter was greater than
270 2 mm for the six sites; and the differences of in number concentration were gradually
271 reflected in each raindrop size bin as the rainfall rate class increased. Observationally,
272 the DSDs of BLG, HS and TL had larger number concentrations in different rainfall
273 rate classes, and the DSD parameters and standard deviations (SDs) were larger,
274 especially for BLG.

275 Table 4. Statistics of several integral DSD parameters for six rain rate classes at six sites.

277

Figure 4. Distribution of mean measured DSD for different rain rate classes at six sites.

278 Figure 5 shows box-and-whisker plots of the normalized intercept parameter
279 $\log_{10}N_w$ and mass-weighted mean diameter D_m for six sites in each rain rate class. The
280 middle line in the box indicates the median. The left and right lines indicate the 25th and
281 75th percentiles. The left and right ends of whiskers indicate the most extreme data
282 points between the 5th and 95th percentiles, except outliers. The median D_m gradually
283 increased with a larger value range as the rain rate class increased, particularly for HS
284 and BLG in class C5 and C6. The median $\log_{10}N_w$ increased in class C1 to C3 and then
285 tended to decrease in class C5 to C6, for which the reduction was obvious at sites with
286 a larger value range, such as HS and BLG. Ma et al. (2019b) also obtained similar
287 conclusions about D_m and $\log_{10}N_w$. The indication was that the increase in rain rate was
288 mainly due to the growth in raindrop size. Also, the change in number concentration
289 may have been caused by the imbalance between the loss of number concentration at
290 small raindrop size and the addition at large raindrop sizes, which in a sense implies a
291 relationship between the collision–coalescence and break–up of raindrops. It is worth
292 noting that the microphysical processes were quite different among the sites, being
293 greatly influenced by the surrounding environment. Because HS and BLG were located
294 in the interior of the mountains and close to the ridge, their dynamics and
295 thermodynamics as well underlying surfaces were thus different from those of other
296 sites.

297

298 Figure 5. Variation of the normalized intercept parameter $\log_{10}N_w$ (a) and the mass-
 299 weighted mean diameter D_m (b) for different rain rate classes at six sites. The three lines
 300 in the boxes are the 25th, 50th and 75th percentiles, from left to right, respectively. The
 301 whiskers at the left and right ends are the 5th and 95th percentiles, respectively. The
 302 colors represent the six sites as in other figures.

303 Figure 6 displays the contribution of different rain rate classes to the total rainfall
 304 at different sites. It is clear that C2 contributed the most to the total rainfall of all sites,
 305 followed by C3, and the sum of the two classes' contribution could reach 60% of the
 306 total rainfall. Compared with the interior and southern-slope sites, C2 and C3
 307 contributed slightly less to sites LB and SD (i.e., the northern slopes), while C5 and C6

308 contributed relatively more to sites LB and SD, indicating that there is a greater
 309 probability of heavy precipitation events on the northern slopes. The DSD parameters
 310 in Table 3 provide a more detailed representation of the rainfall differences between the
 311 three geographical sections of the Qilian Mountains, i.e., the interior, southern slopes
 312 and northern slopes. Meanwhile, it also reflects the characteristics of rainfall in the
 313 eastern and interior sections, such as the eastern section had larger Z and D_m and smaller
 314 $\log_{10}N_w$ and $\log_{10}N_t$ compared to the interior. It is possible that there is a certain spatial
 315 connection between precipitation at the sites, related to factors such as the source of
 316 precipitation vapor, weather system and so on.

317
 318 Figure 6. Proportion of rainfall with different rain rate classes to rain amount at six sites.

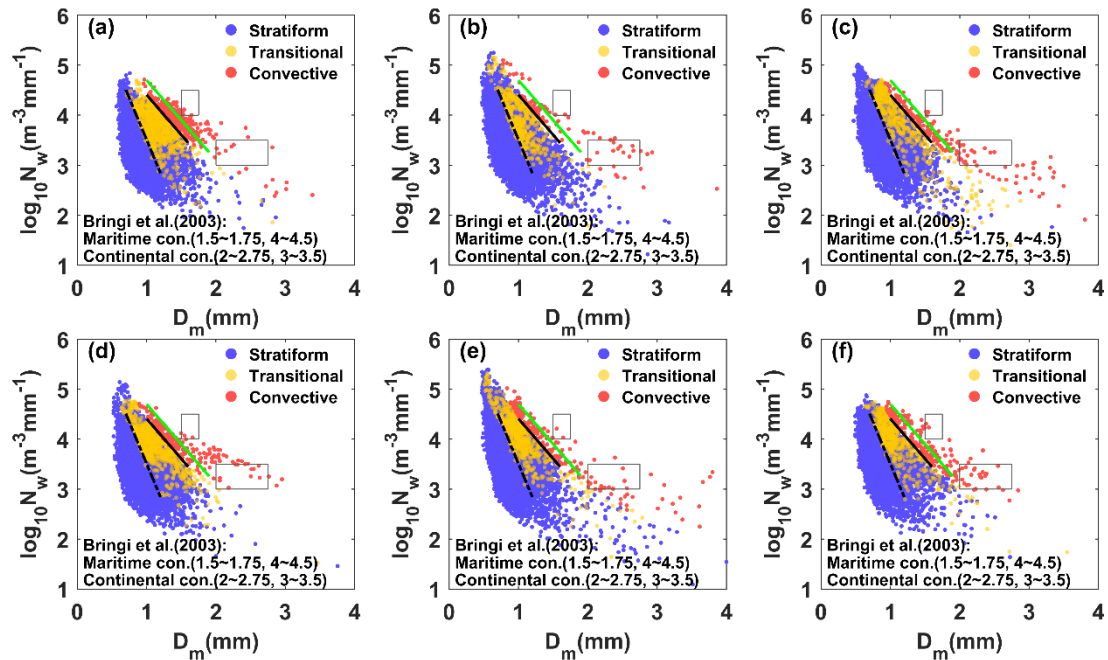

319 3.4 DSD properties for different rain types

320 Previous studies on DSD have shown that there are significant differences in the
 321 DSD of convective and stratiform rainfall in the same climatic region, which has a
 322 substantial impact on the parameterization of NWP and remote sensing observations
 323 (Bringi et al., 2003; Penide et al., 2013). Due to the different physical mechanisms of
 324 convective and stratiform rainfall, it is possible to discuss the differences in
 325 microphysical structures for rainfall types through their DSD. Studies have employed
 326 many different classification methods for rainfall types; example, Testud et al. (2001)
 327 used the rain rate; Chen et al. (2013) combined the rain rate and its SD; and the findings
 328 of Das et al. (2018) were based on the rain rate and radar reflectivity factor. Among
 329 these, the method of Chen et al. (2013) has commonly been used to establish samples
 330 of convective and stratiform rainfall, , but mainly in semi-humid or humid regions with
 331 relatively high rain rate and rainfall. However, the Qilian Mountains are located in the
 332 semi-arid regions of China and far from the sea, where the average rainfall rain and
 333 rainfall are quite different from in semi-humid regions. Therefore, this paper proposes
 334 a new classification method for precipitation applicable to the arid and semi-arid
 335 regions of Northwest China based on the classification ideas of Chen et al. (2013) and
 336 Das et al. (2018).

337 Firstly, the sequences of DSD with continuous 1-min samples more than 10 min

338 are determined, and R_t is defined as the rain rate at time t . In the first case, the R of
339 samples from R_{t-5} to R_{t+5} are all less than 5 mm h^{-1} and their SD is less than 1.5 mm
340 h^{-1} ; in the second case, the R of samples from R_{t-5} to R_{t+5} are greater than or equal to 5
341 mm h^{-1} with more than nine samples and their SD is greater than 1.5 mm h^{-1} ; and in
342 the third case, the situation is the same as the second case but their SD is less 1.5 mm
343 h^{-1} . Secondly, samples satisfying $Z < 20$ and $W < 0.08$ in the second case are removed
344 (Thurai et al., 2016; Das et al., 2018). And then, samples with R_t greater than or equal
345 to 5 mm h^{-1} in the second case are regarded as convective rainfall and samples with R_t
346 less than 5 mm h^{-1} in the second case are regarded as transitional rainfall (the rainfall
347 stage in which convective precipitation develops and declines). Samples in the first case
348 are regarded as stratiform rainfall. Through experiments, the third case does not exist.

349 The $\log_{10}N_w$ and D_m of different rainfall types were different, which were taken as
350 the main research objects. Figure 7 shows the variation of $\log_{10}N_w$ with D_m at different
351 sites. The blue, red and yellow scatter points represent stratiform, convective and
352 transitional rainfall, respectively. Obviously, there are fairly clear boundaries between
353 the scatter points for the different precipitation type events, and the same dividing line
354 can be used to distinguish between the different rainfall types at different sites. The
355 black solid lines were drawn based on visual examination of the data with a slope of
356 approximately -1.60 and intercept of 6.008 to represent the split between stratiform,
357 transitional and convective rainfall in all subplots. The black dashed line can distinguish
358 transitional rainfall (transitional and stratiform rainfall have an overlap area) with a
359 slope of approximately -3.338 and intercept of 6.847 . Note that the dividing line
360 between stratiform and convective rainfall has the same slope as that obtained by Bringi
361 et al. (2003) (solid green line with a slope of -1.6 and intercept of 6.3), who fitted
362 composite results based on disdrometer data and from radar retrievals covering many
363 climate conditions from near the equator to plateau. The $\log_{10}N_w$ and D_m from the
364 figures for stratiform, convective and transitional rainfall are respectively concentrated
365 in the ranges of $3.1\text{--}3.9 \text{ m}^{-3}\text{mm}^{-1}$, $0.75\text{--}1.1 \text{ mm}$; $3.8\text{--}4.2 \text{ m}^{-3}\text{mm}^{-1}$, $1.4\text{--}1.6 \text{ mm}$; 3.6--
366 $4.0 \text{ m}^{-3}\text{mm}^{-1}$, $1.05\text{--}1.2 \text{ mm}$. Compared to the maritime-like cluster and continental-like
367 cluster of convective rainfall proposed by Bringi et al. (2003), the convective events in
368 the Qilian Mountains are more consistent with the continental-like cluster (the gray
369 rectangle with smaller $\log_{10}N_w$ and larger D_m in Fig. 7). There are isolated convective
370 events in the maritime-like cluster, but it is difficult to have more events from the trend
371 between $\log_{10}N_w$ and D_m . This is also consistent with the features of the geographical
372 location of the Qilian Mountains.

373

374

Figure 7. Scatter plot of $\log_{10}N_w$ versus D_m for different rain types at (a) LB, (b) HS, (c) TL, (d)SD, (e)BLG, and (f)DLD. The stratiform cases, convective cases and transitional cases are represented by blue, red and yellow scatter points, respectively. The black dashed lines are the $\log_{10}N_w$ - D_m relationship for stratiform versus convective cases and stratiform versus transitional case.

399

Figure 8 shows the mean DSDs for stratiform, convective and transitional rainfall at the six sites. The range of number concentrations and corresponding raindrop diameters for the three types were significantly different, matching the basic characteristics of DSD. The mean DSDs of stratiform rainfall differed slightly among the sites; convective rainfall had big differences at among the sites; and transitional rainfall presented more differences beginning at larger than 2.2 mm in diameter, which were the expected results. Stratiform rainfall usually has a large horizontal extent and an homogeneous cloud distribution, which makes the DSD characteristics basically the same under the influence of the same cloud system in mountainous areas. However, convective rainfall is related to local thermal and dynamical factors, which could lead to differences in DSD at different sites when considering the complex topography and diverse underlying surfaces in mountainous areas. For example, for convective rainfall, there was a significant increase in the number concentration of raindrops larger than 2.2 mm in diameter at BLG, HS and TL, indicating that these sites are conducive to the development of convective precipitation. Also, the number concentration of small raindrops at BLG and HS were higher than at TL (the southern slope), which may be due to the higher altitude of the interior sites reducing the falling distance of raindrops after exiting the cloud and decreasing the impact of collision on the raindrop evolution. In other words, even for the same rainfall type, the microphysics of rainfall at different sites is still different, depending on the topography and position of the observation point relative to the cloud base.

400

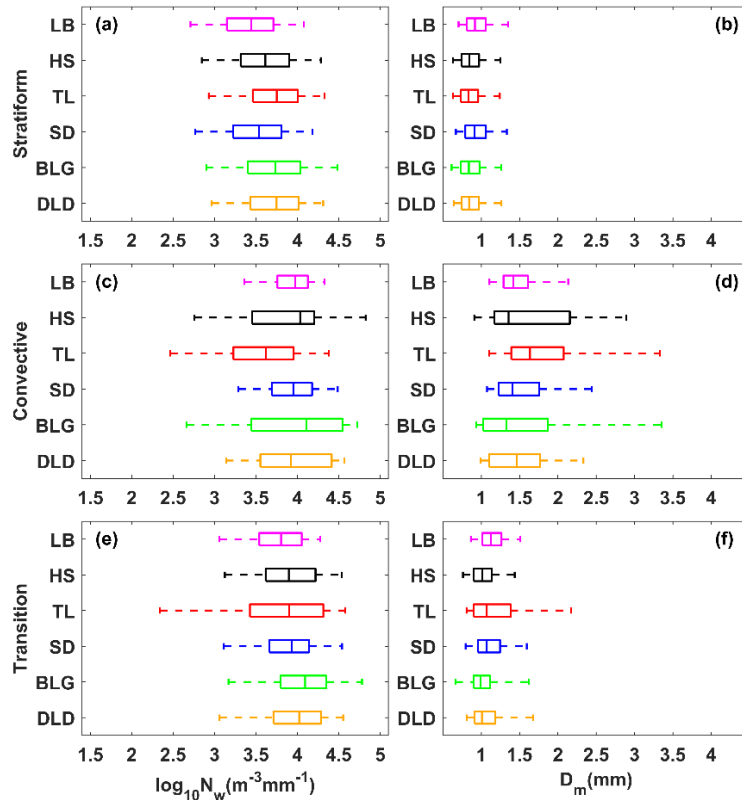

401 Figure 8. Distribution of mean measured DSD for (a) stratiform rainfall, (b) convective
402 rainfall and (c) transitional rainfall at six sites.

403 Figure 9 shows box-and-whisker plots of $\log_{10}N_w$ and D_m for different rain types.
404 The $\log_{10}N_w$ and D_m of stratiform rainfall were smaller than those of convective rainfall
405 but larger than those of transitional rainfall. Sites with a large $\log_{10}N_w$ value range had
406 larger value ranges for D_m ; and sites with a large median $\log_{10}N_w$ had a smaller median
407 D_m , especially at sites HS and BLG for convective rainfall. Based on the mean values
408 of the six sites in Table 5, the DSD characteristics in the Qilian Mountains consist of a
409 larger N_w and smaller D_m due to the melting of tiny, compact graupel, and rimed ice
410 particles (relative to large, low-density snowflakes). Compared with transitional rainfall,
411 the D_m of convective rainfall was obviously larger, indicating that the increase in rain
412 rate in this area is mainly due to the growth in raindrop size. Moreover, on the northern
413 slopes one should consider the increase in number concentration, because the $\log_{10}N_w$
414 of convective rainfall also increased. Note that the number of convective samples on
415 the northern slopes was higher than that of other sites, which corresponds to the
416 speculation regarding the contribution of different rain rate classes. On average, for
417 stratiform rainfall, the dispersion degree of $\log_{10}N_w$ and D_m at different sites was 8.3%
418 and 10.0%, respectively; and for convective rainfall it was 10.4% and 23.4%. The SDs
419 of DSD parameters at sites HS and BLG were relatively large.

Figure 9. As in Fig. 5 but for different rain types at six sites.

424

3.5 Implications for radar rainfall estimation with DSD

425

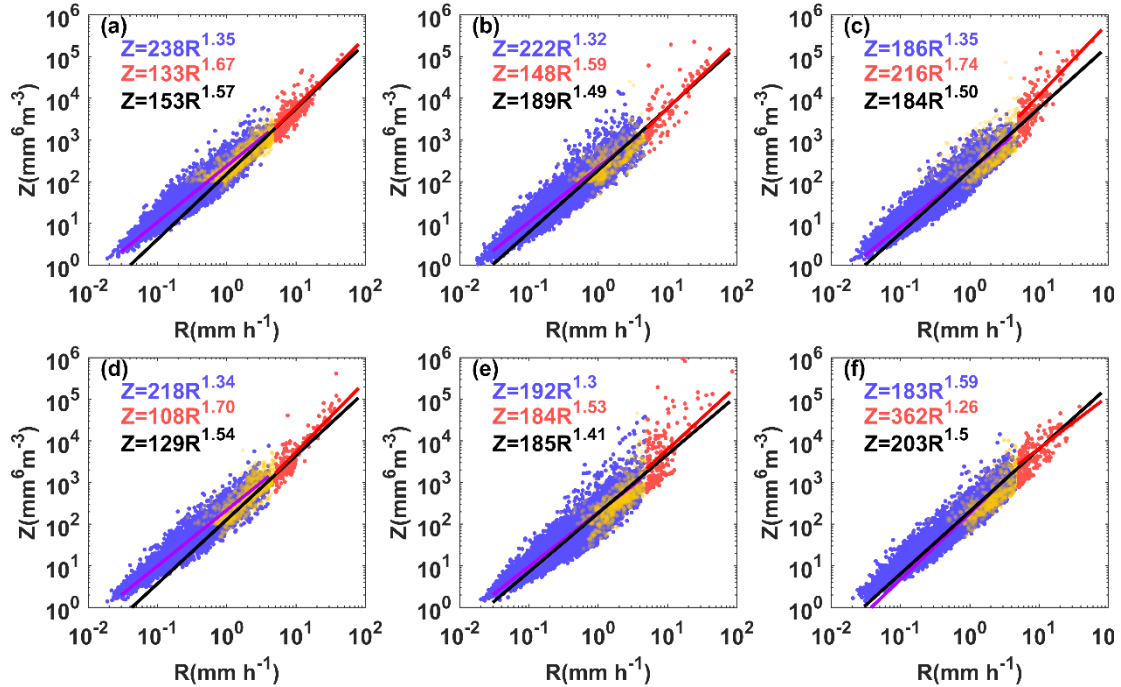

The sixth moment of raindrop diameter is proportional to the radar reflectivity factor and the 3.76th moment is approximately the rain rate (they can be calculated by Equations 4 and 5). Generally, the theoretical basis of QPE for single polarization radar (ground-based or space-based) is the power relationship between the radar reflectivity and rainfall rate ($Z=AR^b$). This makes the coefficients A and exponents b of the power relationship heavily dependent on the variation in DSD. Therefore, it is necessary to obtain the A and b of different sites according to different rainfall types.

432

Figure 10 shows the Z - R scatter plots for different sites and the fitted power-law relationships for different rainfall types. The blue and red scatter points represent stratiform and convective rainfall, respectively. The purple, red and black solid lines indicate the Z - R relationships for stratiform, convective and total rainfall, respectively. It shows that the Z - R scatter points for HS and BLG were relatively scattered around the 5 mm h^{-1} rain rate. Besides, the Z - R relationship of total rainfall underestimated the

437

438 stratiform rainfall at low R values and the convective rainfall at high R values. Based
 439 on the average Z - R relationship using a least-squares method, the dispersion degree of
 440 A and b at different sites was 42.5% and 10.7%, respectively, which reveals there to be
 441 large differences in mountain areas.

442
 443 Figure 10. Scatter plots of Z ($\text{mm}^6 \text{m}^{-3}$) versus R (mm h^{-1}) for three rain types at (a) LB,
 444 (b) HS, (c) TL, (d)SD, (e)BLG, and (f)DLD. The blue, red and yellow scatter points,
 445 represent stratiform, convective and transitional cases, respectively. The purple, red and
 446 black lines denote the Z - R relations. The blue, red and black formula denote stratiform,
 447 convective and total Z - R relationships.

448 In order to compare the six sites Z - R relationships with some standard Z - R
 449 relationships, the results for $Z=300R^{1.4}$ for convective rainfall commonly used in radar,
 450 and $Z=200R^{1.6}$ (i.e., M48) for stratiform rainfall commonly used in midlatitude areas,
 451 are provided in Figure 11. Overall, convective rainfall had smaller values of A and larger
 452 values of b than those of stratiform rainfall (excluding DLD). The A values of
 453 convective rainfall were smaller than the commonly used Z - R relationship with large
 454 differences, but the b values were greater. The distribution of A and b for stratiform
 455 rainfall was relatively concentrated, with A and b ranging from 186–238 and 1.3–1.35,
 456 respectively. The A values of SR were close to those of M48, and the b values were
 457 close to and smaller than the Z - R of global SR. Station DLD had a similar Z - R for
 458 stratiform rainfall with as M48, while its convective rainfall was different from other
 459 sites, with a larger A value (twice as large as other sites) and smaller b value. In addition,
 460 it is clear that the A value of stratiform rainfall increased from the southern slopes to
 461 northern slopes, while the opposite was the case for convective rainfall. Also, the Z - R
 462 relationships of the same section are more consistent, such as those of the interior or
 463 the northern slopes, which have distinct geographic characteristics.

464

465 Figure 11. The A and b values of the Z - R relationships for (a) stratiform rainfall and (b)
 466 convective rainfall at six sites. The purple lines in (a) and cyan lines in (b) correspond
 467 to the global Z - R model ($Z = 295R^{1.49}$ for continental stratiform rainfall and $Z = 278R^{1.54}$
 468 for convective rainfall, respectively) (Ghada et al., 2018). The cyan lines in (a) represent
 469 the midlatitude stratiform rainfall Z - R model ($Z = 200R^{1.60}$, Marshall, 1948); and the
 470 purple lines in (b) represent the convective rainfall Z - R model ($Z = 300R^{1.40}$) applied to
 471 operational weather radar (Fulton et al., 1998).

472 4 Discussion

473 The paper analyses the statistical characteristics of DSD at different sites in the
 474 Qilian Mountains during the rainy season, which not only contain rainfall classes and
 475 rainfall types but more importantly reflect the differences between different sites. The
 476 results from different aspects can be mutually confirmed and have a good representation
 477 of the spatial distribution, serving as a strong factual basis for discussion of the
 478 microphysical structure of precipitation. For example, with the rain rate class rising, the
 479 number concentration of all size bins is increased and the width of DSDs became wider,
 480 which manifested as convective rainfall having a larger rain rate. In spatial terms, the
 481 characteristics of precipitation in the interior of the mountains and on the southern
 482 slopes were closer, whether considering the overall DSD distribution or the
 483 distributions of DSD parameters. However, there were obvious variabilities at the
 484 interior sites for DSD parameters due to the influences of local dynamics and thermal
 485 effects. On the other hand, these characteristics also exhibited some differences between
 486 the interior and eastern sections of the Qilian Mountains, especially in the discussion of
 487 DSD parameters for rainfall classes and rainfall types (s Figures 5 and 9). This spatial
 488 variation in DSD suggests that microphysical processes involved in the DSD are
 489 influenced by complex topography (altitude, mountain alignment) and potentially
 490 related to the source of water vapor, development of precipitation process and
 491 anthropogenic factors.

492 Compared to previous studies that focused on eastern, southern and northern China
 493 as well the Tibetan Plateau, the Qilian Mountains region has its own unique DSD
 494 characteristics and Z - R relationship during the rainy season, including a smaller
 495 raindrop diameter with a higher number concentration. Moreover, the division of
 496 rainfall rate classes in the Qilian Mountains more adequately reflects the DSD
 497 characteristics in each class, unlike when using the classification method of other sites
 498 with larger rainfall rates. More importantly, the proposed classification of stratiform
 499 and convective rainfall can clearly distinguish between the distribution of $\log_{10}N_w$

500 versus D_m in different rainfall types, for which the dividing line (slope of -1.6 and
501 intercept of 6.008) between stratiform and convective rainfall has the same slope as the
502 line (slope of -1.6 and intercept of 6.3) given by Bringi et al (2003). Furthermore,
503 according to this method, it can be easily proven that convective events are more
504 consistent with the continental-like cluster, conforming to the precipitation
505 characteristics of the Qilian Mountains .

506 As mentioned above, the characteristics of DSD mainly describe diameters larger
507 than 0.2 mm, which is limited by the observation instruments being unable to detect
508 small drops of diameter less than 0.2 mm. Therefore, it is not a complete DSD, and the
509 number concentration of small drops of diameter less than 0.5 mm is underestimated.
510 Recent studies have been devoted to improving DSD observations in order to overcome
511 the limitations of disdrometers. A study by Thurai et al. (2017) obtained a more
512 complete DSD by splicing 2DVD and MPS (Meteorological Particle Spectrometer)
513 measurements to observe DSDs and developed a technology to reconstruct the drizzle-
514 mode DSD (Raupach et al., 2019), which a good presentation of the DSD of small
515 raindrops was provided, and important applications were highlighted.

516 **5 Summary and conclusion**

517 Based on six months of DSD data observed over the southern slopes, northern
518 slopes and interior of the Qilian Mountains, the characteristics and differences of DSD
519 were studied, and the $Z-R$ relationships of six sites were discussed. The main
520 conclusions can be summarized as follows:

521

- 522 1. For all rainfall events, the number concentrations of small and large raindrops in
523 the interior and on the southern slopes were greater than that on the northern slopes,
524 while midsize raindrops were less. The DSD of the interior of the mountains
525 showed great variability, mainly in terms of the $\log_{10}N_w$ and D_m (DSD parameters),
526 which was quite different to the case for the northern slopes.
- 527 2. The rainfall rates were divided into six categories based on the DSD characteristics:
528 C1, $R < 0.5$; C2, $0.5 \leq R < 2$; C3, $2 \leq R < 4$; C4, $4 \leq R < 6$; C5, $6 \leq R < 10$; and C6, > 10
529 mm h^{-1} . As the rainfall rate increased, the differences in number concentration of
530 each raindrop size became significantly larger, especially at the interior sites.
531 Besides, classes C5 and C6 made a relatively large contribution to the northern
532 slopes, with a greater probability of heavy precipitation events.
- 533 3. The dispersion degree of $\log_{10}N_w$ and D_m at the six sites was 8.3% and 10.0% for
534 stratiform rainfall and 10.4% and 23.4% for convective rainfall, respectively. It is
535 easier to increase the number concentration of large raindrops in the interior area
536 of the mountains during convective rainfall. Meanwhile, there is a greater increase
537 in the number concentration of raindrops over the northern slopes during
538 convective rainfall.
- 539 4. The dispersion degree of coefficient A and exponent b in the $Z-R$ relationship for
540 the six sites was 42.5% and 10.7% , respectively. Overall, the $Z-R$ relationships of
541 the ipsilateral sites were more consistent; and the A value of stratiform rainfall
542 increased from the southern slopes to northern slopes, while the opposite was true

543 for convective rainfall. The Z - R relationships in stratiform rainfall were similar
544 and generally underestimated by the $Z=200R^{1.6}$ model used for midlatitude
545 stratiform rainfall; and the Z - R relationships for convective precipitation varied
546 greatly at different stations, which were overestimated by $Z=300R^{1.4}$ at lower rain
547 rates values and underestimated at higher rain rates values.

548 This study reveals the microphysical variability of precipitation over the complex
549 topography of the arid and semi-arid regions of Northwest China, which can not only
550 improve local numerical simulations, but also provides a basis for further understanding
551 the differences in DSD characteristics formed at the mesoscale due to topographic
552 factors and the water vapor distribution, etc. This study holds importance as a basis for
553 the future implementation of weather modification techniques, which is of great
554 significance in solving the shortage of water resources in the arid and semi-arid regions.

555 *Data availability.* Disdrometer data used in this study are available by contacting the
556 authors.

557 *Author contributions.* WM conducted the detailed analysis; WZ provided financial
558 support and conceived the idea; MK collated the observation data; all the authors
559 contributed to the writing and revisions.

560 *Competing interests.* The authors declare that they have no conflict of interest.
