22 **Abstract.** Precipitation is the ~~most important~~dominant driver of the hydrological cycle but it is challenging to  
23 ~~estimate accurately measure at suitably high resolution~~ over ~~large global~~ scales ~~using from~~ satellites and models.  
24 Here, we assessed the performance of six global and quasi-global high-resolution precipitation datasets (European  
25 Center for Medium-range Weather Forecast (ECMWF) Reanalysis version 5 ~~ERA5 global reanalysis~~ (ERA5),  
26 Climate Hazards group Infrared Precipitation with Stations version 2.0 (CHIRPS), Multi-Source Weighted-  
27 Ensemble Precipitation version 2.80 (MSWEP), TerraClimate (TERRA), Climate Prediction Centre Unified  
28 version 1.0 (CPCU) and Precipitation Estimation from Remotely Sensed Information using Artificial Neural  
29 Networks-Cloud Classification System-Climate Data Record (PERCCDR)) for hydrological modelling globally  
30 and quasi-globally. We forced the WBMsed global hydrological model with the precipitation datasets to simulate  
31 river discharge from 1983 to 2019 and evaluated the predicted discharge against ~~more than 1800~~1825 hydrological  
32 stations worldwide, using a range of statistical methods. The results show large differences in the accuracy of  
33 discharge predictions when using different precipitation input datasets. Based on evaluation at annual, monthly  
34 and daily time scales, MSWEP followed by ERA5 demonstrated a higher CC and KGE than other datasets for  
35 more than 50% of the stations. Whilst, ERA5 was the second-highest performing dataset, ~~and it showed~~exhibited  
36 the highest error and bias in about 20% of the stations. The PERCCDR is the least well-performing dataset with  
37 ~~large bias (percentage of bias up to 99%) and errors (a normalised root mean square error up to 247%).~~ PERCCDR  
38 ~~only revealed~~show with a higher KGE and CC than the other products in less than 10% of the stations. Even  
39 though MSWEP provided the highest best performance overall, our analysis reveals high spatial variability,  
40 meaning that it is important to consider other datasets in areas where MSWEP showed a lower performance. The  
41 results of this study highlight the importance of, and provide guidance on, the selection of precipitation datasets  
42 for modelling river discharge for a basin, region or climatic zone, as there is no single best precipitation dataset  
43 globally. Finally, the large discrepancy in the performance of the datasets in different parts of the world highlights  
44 the need to improve global precipitation data products.

## 58 1. Introduction

59 Whilst precipitation is one the most important components of the global hydrological cycle and regulates the  
60 climate system (Miao et al., 2019; Sadeghi et al., 2021), it remains one of the most challenging variables to  
61 estimate at a global scale using satellite data and modelling approaches (Michaelides et al., 2009; Kidd and  
62 Levizzani, 2011; Beck et al., 2017a; Ursulak and Coulibaly, 2021). Reliable precipitation data with sufficient  
63 spatial and temporal coverage and accurate representation of extreme events is crucial for various applications.  
64 These include the development of water resource management and planning strategies, hydrological  
65 applications including forecasting hydrological extremes, and climate change analysis (Mehran and  
66 AghaKouchak, 2014; Nguyen et al., 2018; Sadeghi et al., 2021; Acharya et al., 2019). Observed precipitation from  
67 meteorological stations is typically used at local to river basin scale with gauge-based gridded precipitation  
68 datasets, such as from the Global Historical Climatology Network (Menne et al., 2012), developed to study climate  
69 and hydrology over larger scales. However, precipitation from gauges and gauge-based gridded datasets have  
70 several drawbacks such as limited spatial and temporal coverage, prevalence of missing values, and limited  
71 accuracy in sparsely populated and remote areas (Kidd and Levizzani, 2011; Reichle et al., 2011; Kidd et al.,  
72 2017; Sun et al., 2018; Gebrechorkos et al., 2018; Hafizi and Sorman, 2022). In addition, data-sharing policies  
73 have caused significant challenges in obtaining data, particularly in developing countries (Gebrechorkos et al.,  
74 2018; Hafizi and Sorman, 2022).

75 Given the challenges in representing precipitation at global scales, satellite, climate model, and reanalysis-based  
76 precipitation datasets can form the basis for monitoring and prediction of water resources and hydrological  
77 extremes, particularly in data-scarce regions of the world (Sheffield et al., 2018; Dembélé et al., 2020).  
78 Nevertheless, uncertainties and errors in these datasets require careful analysis to assess their suitability for a  
79 specific use. Error in satellite-based precipitation estimates can be due to errors in the sensor measurements, the  
80 frequency of sampling, and the retrieval algorithms, including the representation of cloud physics (Dembélé et al.,  
81 2020; Laiti et al., 2018; Alazzy et al., 2017). Climate model-based datasets, including reanalyses, have large  
82 uncertainty due to their coarse spatial resolution and ambiguity associated with model parameters (Gebrechorkos  
83 et al., 2018; AL-Falahi et al., 2020; Dembélé et al., 2020; Her et al., 2019). Reanalysis datasets may correct for  
84 some of these errors via the assimilation of observational data, but this comes with its own uncertainties due to  
85 the error characteristics of the assimilated observations and the assimilation scheme (Sheffield et al., 2006; Parker,  
86 2016). In hydrological modelling, errors and biases in precipitation data result in poor representation of the  
87 hydrological responses and affect applications (Maggioni and Massari, 2018; Zambrano-Bigiarini et al., 2016).  
88 For example, according to Bárdossy et al. (2022), uncertainty in precipitation can lead to hydrological model  
89 errors of up to 50%. Hence, it is important to assess the quality and accuracy of the precipitation products before  
90 using them in global or basin-scale hydrological models. In data-limited regions, hydrological models driven by  
91 precipitation datasets developed from satellite sources, reanalysis or climate models are the only plausible way to  
92 represent the terrestrial water cycle (van Huijgevoort et al., 2013).

93 Over the last few decades, several global and quasi-global precipitation datasets have been developed that address  
94 some of these challenges and can be used to drive hydrological models at regional and global scales. These  
95 precipitation datasets differ in terms of their spatial resolution, spatial coverage (e.g., global or regional), data

96 sources (e.g., gauge, satellite, reanalysis, and radar), temporal resolution (e.g., sub-daily and daily), and length of  
97 record. It is therefore important to evaluate the accuracy of the datasets before they are used to drive global or  
98 regional scale hydrological models. Most studies have evaluated precipitation datasets using observed data from  
99 field-based meteorological stations at a range of scales (e.g., Beck et al., 2017a; Gebrechorkos et al., 2018; Xiang  
100 et al., 2021; Sun et al., 2018; Hong et al., 2022; Wati et al., 2022; AL-Falahi et al., 2020; Ahmed et al., 2019;  
101 Fallah et al., 2020). Hydrological models have also been used to assess the quality of the precipitation dataset by  
102 comparing simulated and observed discharge across different spatial scales (e.g., Mazzoleni et al., 2019; Beck et  
103 al., 2017a; Zhu et al., 2018; Raimonet et al., 2017; Guo et al., 2018; Wang et al., 2020; Salehi et al., 2022; Zhu et  
104 al., 2018; Seyyedi et al., 2015). In principle, this latter approach is able to identify the precipitation datasets which  
105 best represent hydrological variability including extremes, even in catchments where there have been multiple  
106 drivers of change.

107 There are a limited number of studies assessing multiple precipitation datasets for global hydrological model  
108 applications (Voisin et al., 2008; Beck et al., 2017a; Mazzoleni et al., 2019). Voisin et al. (2008) conducted a  
109 global-scale evaluation of two precipitation products for hydrological modelling. Beck et al., (2017a) compared  
110 the performance of ~~multiple-22~~ precipitation datasets (e.g., ~~the Climate Hazards group Infrared Precipitation with~~  
111 ~~Stations (CHIRPS, version 2.0), Multi-Source Weighted Ensemble Precipitation (MSWEP, version 2.0),~~  
112 ~~European Centre for Medium-range Weather Forecasts ReAnalysis Interim (ERA Interim), and National Centers~~  
113 ~~for Environmental Prediction Climate Forecast System Reanalysis (NCEP-CFSR))~~ for global hydrological  
114 modelling. Mazzoleni et al. (2019) evaluated multiple-18 different precipitation datasets including MSWEP  
115 (Version 2.1) and CHIRPS in eight river basins on different continents. Both Beck et al. (2017a) and Mazzoleni  
116 et al. (2019) found that merged satellite-observation precipitation products showed the best performance compared  
117 to satellite-only products. These studies exclusively concentrate on a daily time scale, evaluating performance  
118 solely through the Nash-Sutcliffe Efficiency (NSE). Neither study extends ~~theirs~~ assessment to monthly and  
119 annual time scales, and notably, they do not assess the hydrological extremes, which in hydrological terms are  
120 ~~often~~ considered important to capture. Here, we build upon the work by Beck et al., (2017a) by adding recently  
121 developed high-resolution precipitation datasets. These include -such as- the European CenterCentre for Medium-  
122 range Weather Forecast (ECMWF) Reanalysis version 5 (ERA5) (Hersbach et al., 2020), TerraClimate  
123 (Abatzoglou et al., 2018), ~~and~~ Precipitation Estimation from Remotely Sensed Information using Artificial Neural  
124 Networks-Cloud Classification System-Climate Data Record (~~PERCCDRPERSIANN-CCS-CDR~~, Sadeghi et al.,  
125 2021) and the latest Multi-Source Weighted-Ensemble Precipitation MSWEP-version (2.80) (MSWEP). These  
126 additions significantly broaden the scope of ~~our~~ this study when compared to earlier efforts, offering a diverse  
127 range of products with distinct methodologies. In addition, herein we use multiple statistical metrics to evaluate  
128 the performance of the precipitation products for hydrological modelling at daily, monthly and annual time scales  
129 and for daily extremes, which represents a current gap in the modelling literature.

130 The aim of this study is to undertake a comprehensive evaluation, spanning various temporal and spatial scales,  
131 to examine how different input precipitation datasets impact the predictions of a global hydrological model. We  
132 assess six high-resolution precipitation datasets, each with records spanning over 30 years. A comprehensive and  
133 physically based gridded global hydrological model (WBMsed; Cohen et al., (2013)) is used to simulate river  
134 discharge globally. The objective is not to evaluate the absolute performance of the hydrological model, which

135 can be influenced by local factors, rather our focus is on comparing the relative performance of these six  
136 precipitation datasets at individual locations. The modelled discharge, derived from the six precipitation datasets,  
137 is assessed across the various time scales by comparing it with observed discharge data collected from 1825 river  
138 gauge stations worldwide. Furthermore, we assess the performance of the precipitation products by examining  
139 their accuracy in representing a range of daily extreme precipitation events ~~across various percentiles~~. In summary,  
140 this research offers a thorough evaluation of ~~a this set of~~ diverse set precipitation products, spanning from daily  
141 extreme events to annual time scales, providing an invaluable resource for selecting appropriate basin-to-regional-  
142 to-global scale inputs for hydrological modelling applications.

## 143 2. Data and methods

144 In the following sections, we outline the various input and evaluation datasets which were used within the  
145 WBMsed hydrological modelling framework. The statistical evaluation methods used to assess the results are also  
146 outlined.

### 147 2.1. ~~Input global and quasi-global pP~~precipitation datasets

148 The precipitation datasets used herein are selected based on their length of record (>30 years period), ~~and~~ spatial  
149 coverage (global and quasi-global) and recommendations from previous research (Beck et al., 2017a) (Table 1).  
150 Based on the findings of Beck et al. (2017a), datasets with low performance were excluded, while those  
151 demonstrating the highest performance, such as MSWEP and Climate Hazards group Infrared Precipitation with  
152 Stations version 2.0 (CHIRPS), were retained, and new datasets were also incorporated. The selected precipitation  
153 datasets are the ERA5 ~~global reanalysis (ERA5)~~, ~~Climate Hazards group Infrared Precipitation with Stations~~  
154 ~~version 2.0 (CHIRPS)~~, ~~Multi Source Weighted Ensemble Precipitation version 2.80 (MSWEP)~~, TerraClimate  
155 (TERRA), Climate Prediction Centre Unified version 1.0 (CPCU), and ~~Precipitation Estimation from Remotely~~  
156 ~~Sensed Information using Artificial Neural Networks Cloud Classification System Climate Data Record~~  
157 ~~(PERCCDR)~~. Due to their spatial coverage, CHIRPS and PERCCDR are evaluated only up to latitudes of 50°N  
158 and 60°N, respectively (Table 1). Each dataset was subsequently used to force the WBMsed hydrological model,  
159 to generate streamflow estimates. The availability of these datasets with longer records enables the assessment of  
160 long-term hydrological changes at global, regional, and catchment scales.

161 ERA5 is the fifth generation European Centre for Medium-Range Weather Forecasts (ECMWF) reanalysis data  
162 available globally from 1940 to present (Hersbach et al., 2020). ERA5 combines modelled data and observations  
163 to create a complete and consistent global climate dataset using advanced data assimilation methods. ERA5  
164 provides improved precipitation representation such as the inclusion of tropical cyclones when compared to the  
165 ERA-Interim (He et al., 2020; Jiao et al., 2021). In addition, ERA5-Land, a subset of ERA5 focusing on land  
166 areas, delivers more detailed climate information is available at higher spatial resolution (0.1°) from 1950 to the  
167 present compared to ERA5 (Hersbach et al., 2020). Here, ERA5-Land (referred to as ERA5) is used to evaluate  
168 its performance for global hydrological modelling. The data is freely available from Copernicus Climate Data  
169 Store (<https://cds.climate.copernicus.eu/cdsapp#!/dataset/reanalysis-era5-land?tab=overview>).

170 CHIRPS is a high-resolution (0.05°) quasi-global rainfall product primarily developed for monitoring droughts  
171 and global environmental changes (Funk et al., 2015). CHIRPS provides coupled gauge-satellite precipitation  
172 estimates with a 0.05° spatial resolution and long-period records. The product is developed by combining satellite-  
173 only Climate Hazards group Infrared Precipitation (CHIRP), Climate Hazards group Precipitation climatology  
174 (CHPclim), and data from ground stations. CHIRP and CHPclim were developed based on calibrated infrared  
175 cold cloud duration (CCD) precipitation estimates and ground station data from the Global Historical Climate  
176 Network (GHCN). The product is available at the Climate Hazards Group (<https://www.chc.ucsb.edu/data/chirps/>)  
177 on daily, 10-day, and monthly timescales from the 1981-near present. Due to its availability at high spatial and  
178 temporal resolution, CHIRPS is widely used in hydrological studies (Luo et al., 2019; Gebrechorkos et al., 2020;  
179 Geleta and Deressa, 2021; Wang et al., 2021; Opere et al., 2022; Day and Howarth, 2019; Gebrechorkos et al.,  
180 2019) and modelling of hydrological extremes such as droughts and floods (Chen et al., 2020; Mianabadi et al.,  
181 2022; Peng et al., 2020).

182 MSWEP is a global high-resolution (0.1°) precipitation product developed by merging multiple datasets such as  
183 ground stations (~77,000), satellite-based rainfall estimates, and reanalysis data (Beck et al., 2019b). MSWEP  
184 ~~includes was developed by merging station data, from the Global Historical Climatology Network Daily (GHCN-~~  
185 ~~D), Global Summary of the Day (GSOD), Global Precipitation Climatology Centre (GPCC), and WorldClim;~~  
186 ~~satellite datasets from the Global Satellite Mapping of Precipitation (GSMaP), Tropical Rainfall Measuring~~  
187 ~~Mission (TRMM) Multi-satellite Precipitation Analysis (TMPA-3B42RT), Climate Prediction Center morphing~~  
188 ~~technique (CMORPH), and Gridded Satellite (GridSat);~~ and reanalysis datasets ~~such as the Japanese 55-year~~  
189 ~~Reanalysis (JRA-55) and European Centre for Medium Range Weather Forecasts (ECMWF) interim reanalysis~~  
190 ~~(ERA-Interim)~~ (Beck et al., 2017b, 2019b). MSWEP has been widely used in regional and global scale  
191 hydrological studies such as for floods and droughts (Gu et al., 2023; Gebrechorkos et al., 2022b; Reis et al., 2022;  
192 Wu et al., 2018; Sun et al., 2022; Gebrechorkos et al., 2022c; Xiang et al., 2021; López López et al., 2017) and  
193 for developing high-resolution global scale hydrological extreme and climate datasets and regional drought  
194 monitoring (Gebrechorkos et al., 2023, 2022a; Li et al., 2022b). MSWEP is available from 1979-present at  
195 multiple timescales (e.g., 3 hourly) and can be accessed from the GloH2O website  
196 (<https://www.gloh2o.org/mswep/>).

197 TerraClimate (TERRA) is a high-resolution (0.04°) terrestrial monthly climate (e.g., precipitation and  
198 temperature) and climatic water-balance dataset available from 1958-2020 (Abatzoglou et al., 2018). TERRA was  
199 developed by combining high and coarse spatial resolution datasets such as WorldClim climatological normals  
200 and Climatic Research Unit gridded Time Series (CRU TS) and JRA-55, respectively. The data was evaluated  
201 against ground observation from the Historical Climate Network and exhibited better performance than the CRU-  
202 TS (Abatzoglou et al., 2018). The monthly climate and climatic water balance is available from the Climatology  
203 Lab website (<https://www.climatologylab.org/>).

204 CPCU is a gauge-based analysis of daily precipitation datasets available globally from 1979 to present at a spatial  
205 resolution of 0.5° (Chen et al., 2008). CPCU is the product of the CPC Unified Precipitation project at NOAA  
206 Climate Prediction Center. The product uses data from more than 30,000 (1979-2005) and 17,000 (2006-present)  
207 stations. The CPCU data is publicly available at the NOAA Physical Sciences Laboratory (PSL,

208 [https://downloads.psl.noaa.gov/Datasets/cpc\\_global\\_precip/](https://downloads.psl.noaa.gov/Datasets/cpc_global_precip/)) and has been used for hydrological and climate  
 209 studies (Beck et al., 2017a; Zhu et al., 2021; Hou et al., 2014).

210 The PERCCDR is a quasi-global (latitude from 60°S to 60°N) dataset developed at the University of California  
 211 (Sadeghi et al., 2021). PERCCDR provides precipitation estimates at high spatial (0.04°) and temporal (3-hourly)  
 212 resolutions from 1983 to present. The dataset is developed using the rain rate output from the PERSIANN-CCS  
 213 model, which uses GridSat-B1 IR and NOAA Climate Prediction Center (CPC-4km) IR data. Compared to other  
 214 PERSIANN precipitation datasets, PERCCDR provides a realistic representation of precipitation extremes  
 215 globally and shows better agreement with CPCU precipitation (Sadeghi et al., 2021). The PERCCDR has been  
 216 used in hydrological studies (Salehi et al., 2022; Eini et al., 2022) and is freely available from the Center for  
 217 Hydrometeorology and Remote Sensing (CHRS) Data Portal (<https://chrsdata.eng.uci.edu/>).

218 Table 1. The six precipitation datasets used in this study, their spatial and temporal resolution, spatial coverage  
 219 and data sources.

Abbreviation	Full name	Spatial resolution and coverage	Temporal resolution	Temporal coverage	Data source	Reference
ERA5	ECMWF (European Centre for Medium-Range Weather Forecasts) Reanalysis V5	0.1°, global	Sub-daily	1979-present	Gauge and reanalysis	(Hersbach et al., 2020)
CHIRPS	Climate Hazards group Infrared Precipitation with Stations (CHIRPS) version 2.0	0.05°, quasi global (50°S-50°N)	Daily	1981-present	Gauge, satellite, and reanalysis	(Funk et al., 2015)
MSWEP	Multi-Source Weighted-Ensemble Precipitation (MSWEP) version 2.80	0.1°, global	Daily	1979-present	Gauge, satellite, and reanalysis	(Beck et al., 2019b)
TERRA	TerraClimate	0.042°, global	Monthly	1958-present	Gauge and reanalysis	(Abatzoglou et al., 2018)
CPCU	Climate Prediction Centre (CPC) Unified V1.0	0.5°, global	Daily	1979-present	Gauge only	(Chen et al., 2008)
PERCCDR	Precipitation Estimation from Remotely Sensed Information using	0.04°, Quasi global	Sub-daily	1983-present	Gauge and satellite	(Sadeghi et al., 2021)

	Artificial Networks-Cloud Classification Climate Data (PERSIANN-CCS-CDR)	Neural System- Record	(60°S- 60°N)				
--	--	-----------------------------	-----------------	--	--	--	--

220 **2.2. WBMsed hydrological model**

221 The WBMsed (Cohen et al., 2013, 2014) hydrological model is used to assess the performance of the different  
222 precipitation datasets for hydrological modelling globally. WBMsed is a global-scale hydrogeomorphic model,  
223 an extension of the WBMplus global hydrology model (Wisser et al., 2010), which is part of the FrAMES  
224 biogeochemical modelling framework (Wollheim et al., 2008). The WBMplus model is one of the first Global  
225 Hydrological Models (GHMs) applied to a global domain (Cohen et al., 2013; Grogan et al., 2022). The model  
226 represents the major hydrological cycle components of the land surface and tracks the balances and fluxes between  
227 the atmosphere, surface water storages, vegetation, runoff, and groundwater (Grogan et al., 2022). The model  
228 includes hydrological infrastructure (e.g., dams), agricultural water requirements, and domestic and industrial  
229 water uses. A ~~high-resolution~~-gridded river network connects grid cells, which allows the routing of fluxes  
230 downstream (e.g., streamflow). The model requires several climate datasets as input in addition to precipitation,  
231 including temperature, humidity, air pressure, and wind speed (Table S1). Additional parameters such as field  
232 capacity, rooting depth, and riverbed slope are used to drive the model.

233 We use an identical model setup to that used by Cohen et al., (2022) with all input datasets as detailed in Cohen  
234 et al. (2013). ~~with Updates include to air temperature which used the~~ daily ERA5 air temperature (Hersbach et  
235 al., 2020) ~~dataset~~ re-gridded at 10 arc-minutes resolution, ~~;~~ reservoir capacity from —global reservoir and dam  
236 database (GRanD v1.3; Lehner et al., (2011)), ~~;~~ ~~and flow network~~ and a 6 arc-minute HydroSTN30 network  
237 ~~which is a derivative derived~~ from HydroSHEDS (Lehner et al., 2008) high-resolution gridded network for flow  
238 network (Lehner et al., 2008). In addition, we used each of our six input precipitation datasets, ERA5, CHIRPS,  
239 MSWEP, TERRA, CPCU, and PERCCDR in turn, keeping all other parameters and inputs the same. All the input  
240 precipitation datasets are bilinearly interpolated to the same spatial resolution of 0.1°. Even though WBMsed can  
241 disaggregate monthly time series into daily, TERRA (only available at monthly resolution, see Ttable 1) is  
242 evaluated on monthly and annual time scales, whilst all other datasets are evaluated at daily, monthly and annual  
243 time scales. ~~in addition~~. WBMsed simulations were run at 0.1° (~11km at the equator) spatial and daily and  
244 monthly temporal resolutions. Several WBMsed streamflow validation analyses have been reported previously  
245 (e.g., Cohen et al., 2022; Dunn et al., 2019; Cohen et al., 2014, 2013; Moragoda and Cohen, 2020), which indicate  
246 that the model represents the long-term average observed streamflow globally. It is important to note that this  
247 study assesses the precipitation datasets without calibration of the WBMsed model for each precipitation dataset,  
248 which could theoretically improve their performance in replicating observed river discharge. ~~Cohen et al. (2022)~~  
249 ~~report R<sup>2</sup>=0.99 in 30-year average prediction against USGS gauge data and a global river dataset.~~

### 250 2.3. Observed river discharge from ground stations

251 Observed daily and monthly river discharge used to evaluate the hydrological model were obtained from the  
252 Global Runoff Data Centre (GRDC, 2023). The GRDC is an international data archive  
253 (<https://www.bafg.de/GRDC/>), which hosts data for over 10,000 hydrological stations. The number of stations  
254 with a length of record greater than 10 years during the evaluation period (1981-2019) are limited. Here, we  
255 consider stations with a minimum record length of 10 years, allowing for missing values within this period. Due  
256 to the spatial resolution of the input datasets and the model simulations (~11x11 km), we only consider stations  
257 with a catchment area of greater than 100 km<sup>2</sup>. Overall, 1825 suitable stations were identified with daily and  
258 monthly records, largely in North and South America, Europe and Australia, with very few stations in Africa and  
259 Asia (Figure 1).

### 260 2.4. Evaluation metrics

261 Several methods are used to assess the modelled discharge using the streamflow observations: the Pearson  
262 correlation coefficient (CC, Eq. 1), Kling-Gupta Efficiency (KGE, Eq. 2) (Gupta et al., 2009), Root-Mean-Square  
263 Error (RMSE, Eq.3) and Percentage of bias (Pbias, Eq.4). CC measures the linear relationship between observed  
264 discharge and simulated discharge, focusing primarily on the degree of association between the two datasets. It is  
265 particularly useful for assessing the strength and direction of this relationship, highlighting how well the model  
266 captures the variability in discharge (Moazami et al., 2013). KGE is a comprehensive metric that evaluates the  
267 overall agreement between observed and simulated streamflow, considering similarities in variability, amplitude,  
268 and timing. It provides an assessment of the model's ability to capture both the magnitude and temporal dynamics  
269 of the observed discharge (Gupta et al., 2009). RMSE measures the average magnitude of the differences between  
270 observed and simulated discharge, providing a measure of the overall goodness of fit. Moreover, the percentage  
271 of bias is used to quantify the systematic overestimation or underestimation of discharge by the model compared  
272 to observations (Moazami et al., 2013). A KGE value of 1.0 indicates a perfect match between the observed and  
273 simulated discharge, whereas values lower than -0.41 show that the model is worse than using the mean of the  
274 observed discharge as a predictor (Knoben et al., 2019). For spatial comparison, the RMSE is normalised by the  
275 standard deviation of the observed data (NRMSE; Eq. 5).

$$276 \quad CC = \frac{\sum_{i=1}^N (M_i - \bar{M}) * (O_i - \bar{O})}{\sqrt{\sum_{i=1}^N (M_i - \bar{M})^2} * \sqrt{\sum_{i=1}^N (O_i - \bar{O})^2}} \quad (1)$$

$$277 \quad KGE = 1 - \sqrt{(r - 1)^2 + (\alpha - 1)^2 + (\beta - 1)^2} \quad (2)$$

$$278 \quad RMSE = \sqrt{\frac{\sum_{i=1}^N (O_i - M_i)^2}{N}} \quad (3)$$

$$279 \quad Pbias = \frac{\sum_{i=1}^N (M_i - O_i)}{\sum_{i=1}^N O_i} * 100 \quad (4)$$

$$280 \quad NRMSE = \frac{RMSE}{SD} * 100 \quad (5)$$

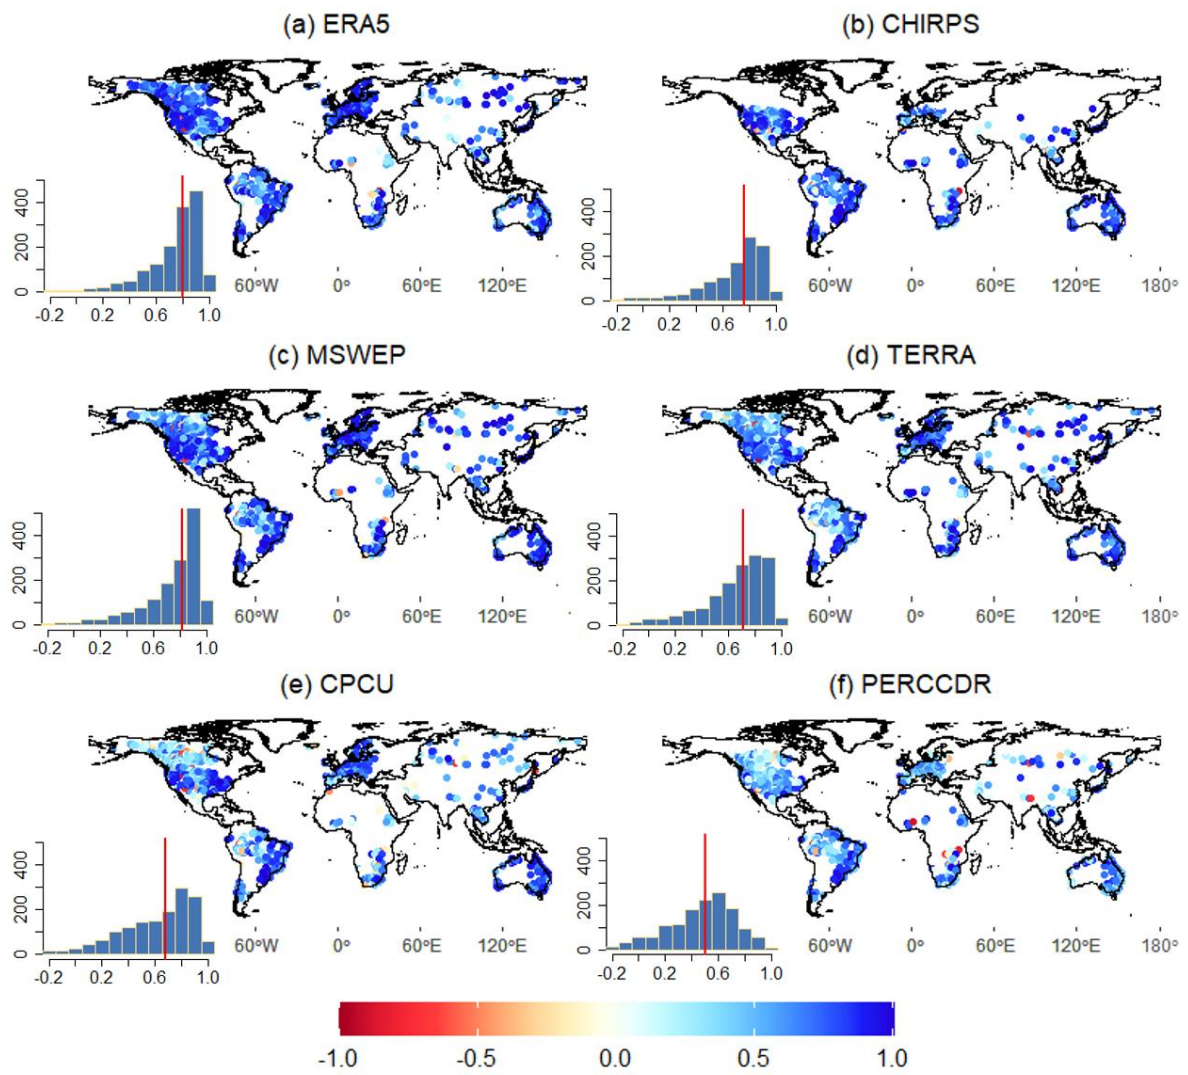

281 where  $r$  is the linear correlation between observed (O) and modelled (M) discharge and  $\alpha$  and  $\beta$  are the variability  
282 and bias ratios, respectively. The NRMSE and SD are the normalised RMSE and standard deviation, respectively.  
283 To assess the performance of the precipitation datasets for representing daily hydrological extremes, the 90<sup>th</sup> (Q10)  
284 and 10<sup>th</sup> (Q90) percentile are used, which indicates high and low flows, respectively. To derive high and low flow  
285 thresholds from a daily flow time series, the data is first arranged in ascending order. The 90<sup>th</sup> percentile (Q10) is  
286 then determined as the flow value above which just 10% of the daily flows lie, representing high-flow  
287 conditions. Similarly, the 10<sup>th</sup> percentile (Q90) represents the flow value below which 90% of the daily  
288 flows occur, indicating low-flow conditions. The Q10 and Q90 represent the streamflow value that is equalled or  
289 exceeded 10% and 90% of the time, respectively.

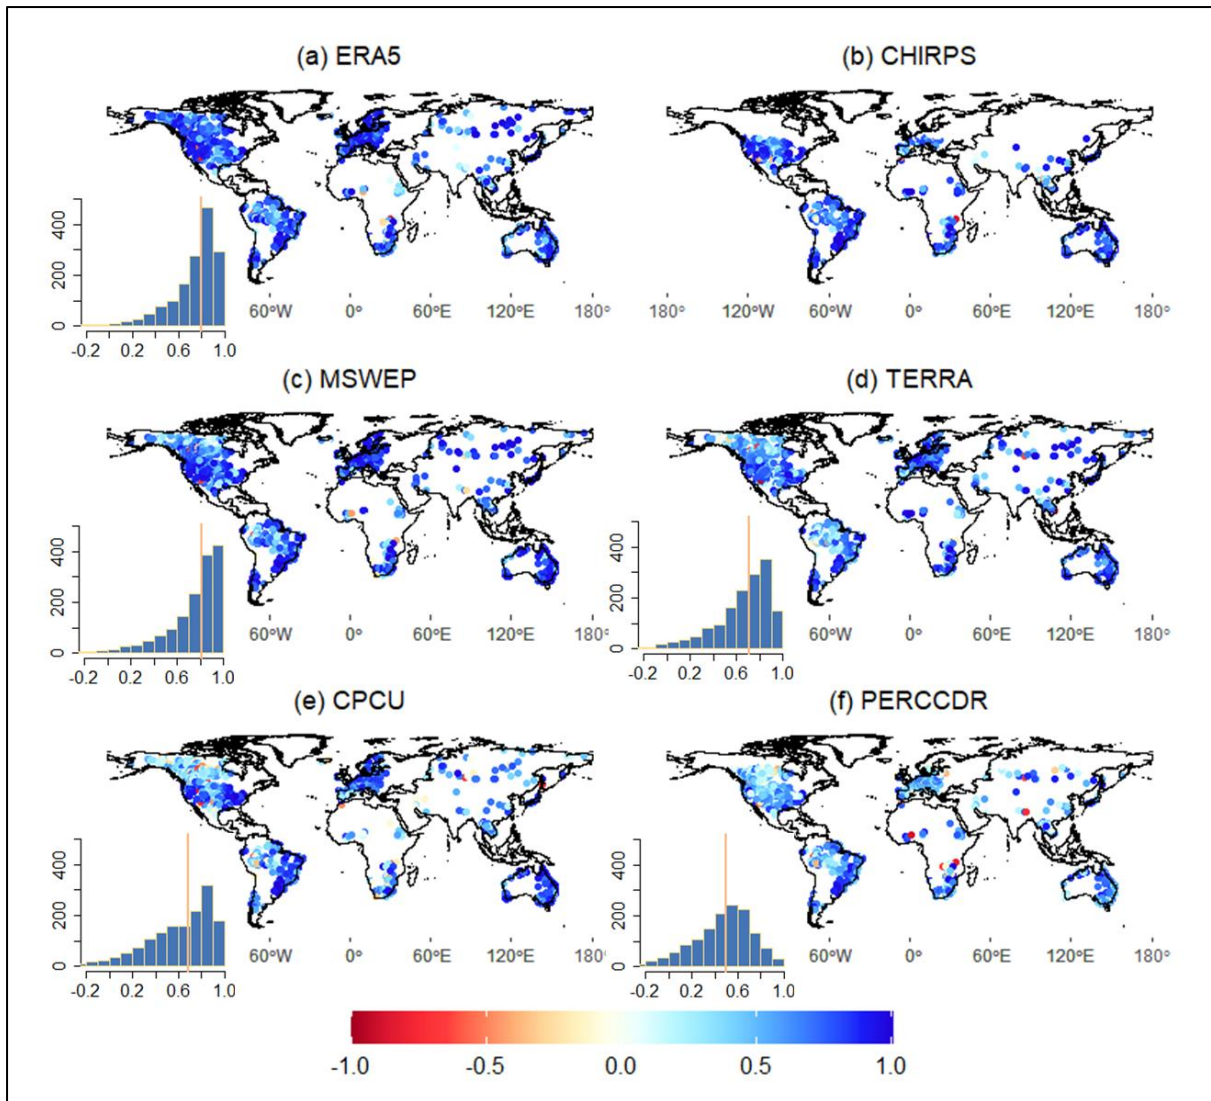

### 290 3. Results

291 ~~The performance of the six different precipitation datasets in simulating discharge is evaluated at annual, monthly~~  
292 ~~and daily time steps and for extremes during the period 1983–2019. The WBMsed output discharge forced by the~~  
293 ~~six precipitation datasets is referred to as ERA5, CHIRPS, MSWEP, TERRA, CPCU, and PERCCDR below.~~

#### 294 3.1. Performance of the six precipitation datasets for annual discharge prediction

295 The temporal correlation coefficient (CC) between the observed and simulated annual discharge based on the six  
296 precipitation datasets is summarised in Figure 1. Most of the datasets, particularly ERA5, MSWEP, and CHIRPS,  
297 showed a high CC in basins of Europe (e.g., Danube basin), South America (e.g., Rio de la Plata-Parana), North  
298 America and Australia (e.g., Murray-Darling). MSWEP and ERA5 showed the highest CC for 34% and 32% of  
299 the stations, respectively, followed by CPCU and CHIRPS. The TERRA and PERCCDR were the least well-  
300 performing datasets with lower CC overall, and a higher CC than other datasets for less than 9% of stations. The  
301 median CC of MSWEP and ERA5 is 0.82 and 0.8, respectively. MSWEP and TERRA showed lower Pbias and  
302 NRMSE compared to the other datasets (Figures S1 and S2). ERA5 and PERCCDR showed a high NRMSE (up  
303 to 247%) and Pbias (up to 99%) for more than 46% of stations. Similar to the CC, ERA5 and MSWEP  
304 outperformed the other datasets for KGE, with higher values for 32% and 27% of stations, respectively. The  
305 performance of MSWEP and ERA5 is higher in basins of Europe, South America, and Australia compared to Asia  
306 and Africa. The median KGE values of ERA5 and MSWEP are 0.33 and 0.32, respectively (Figure 2). The  
307 PERCCDR and CPU demonstrate high KGE only in about 9% of the stations, with median values of 0.10 and  
308 0.13, respectively. Based on the annual CC and KGE, there is no single precipitation dataset that is best  
309 everywhere, and even the least well-performing dataset overall shows better performance in some stations (Figure  
310 3). Figure 3 summarizes the spatial representation of precipitation dataset performance, highlighting the individual  
311 datasets exhibiting the highest CC and KGE values at each observation point.

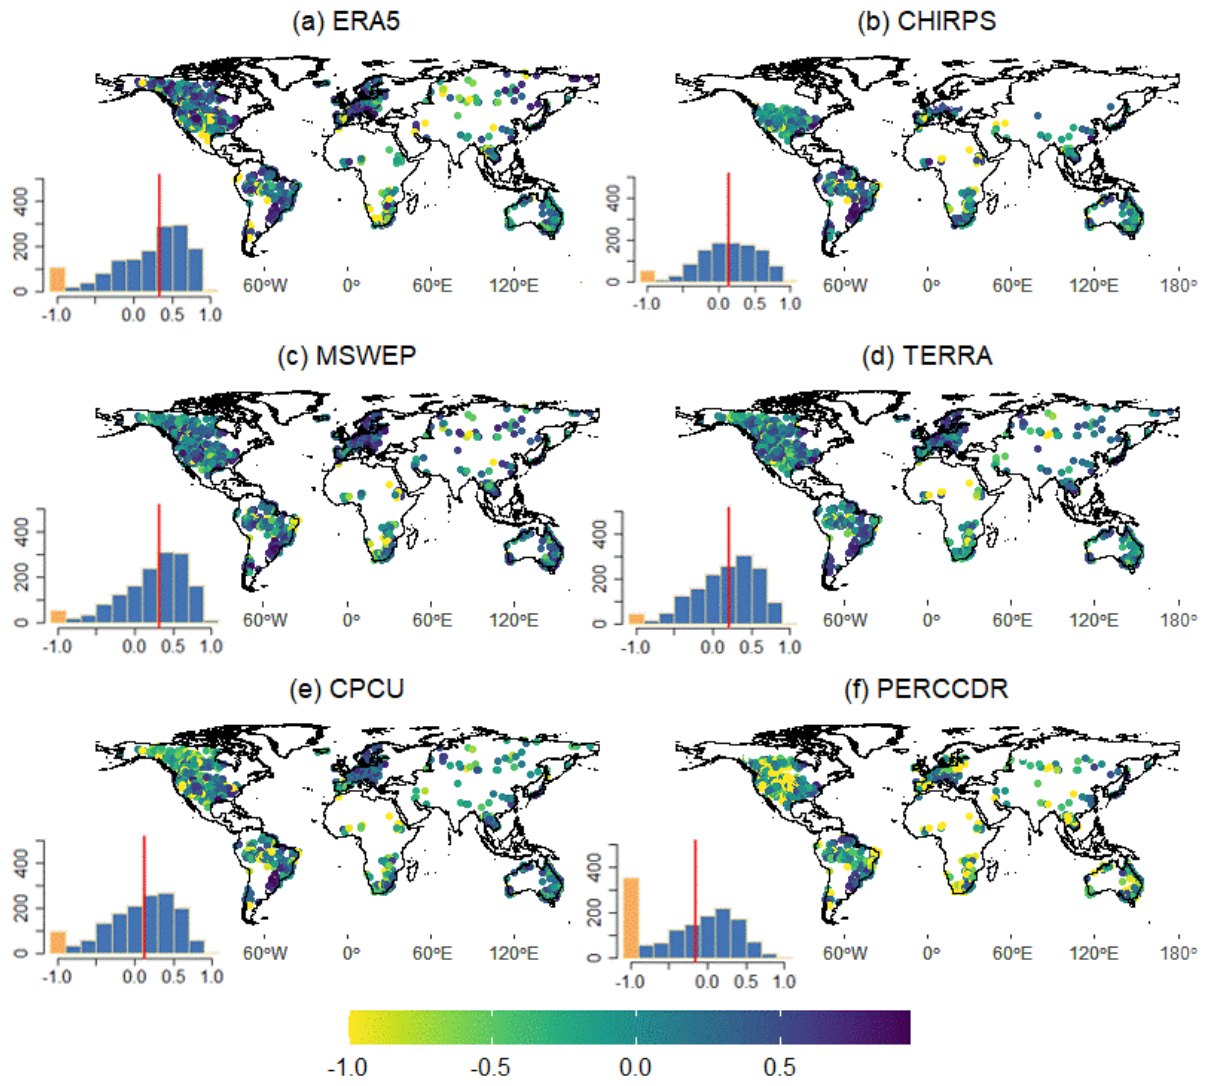

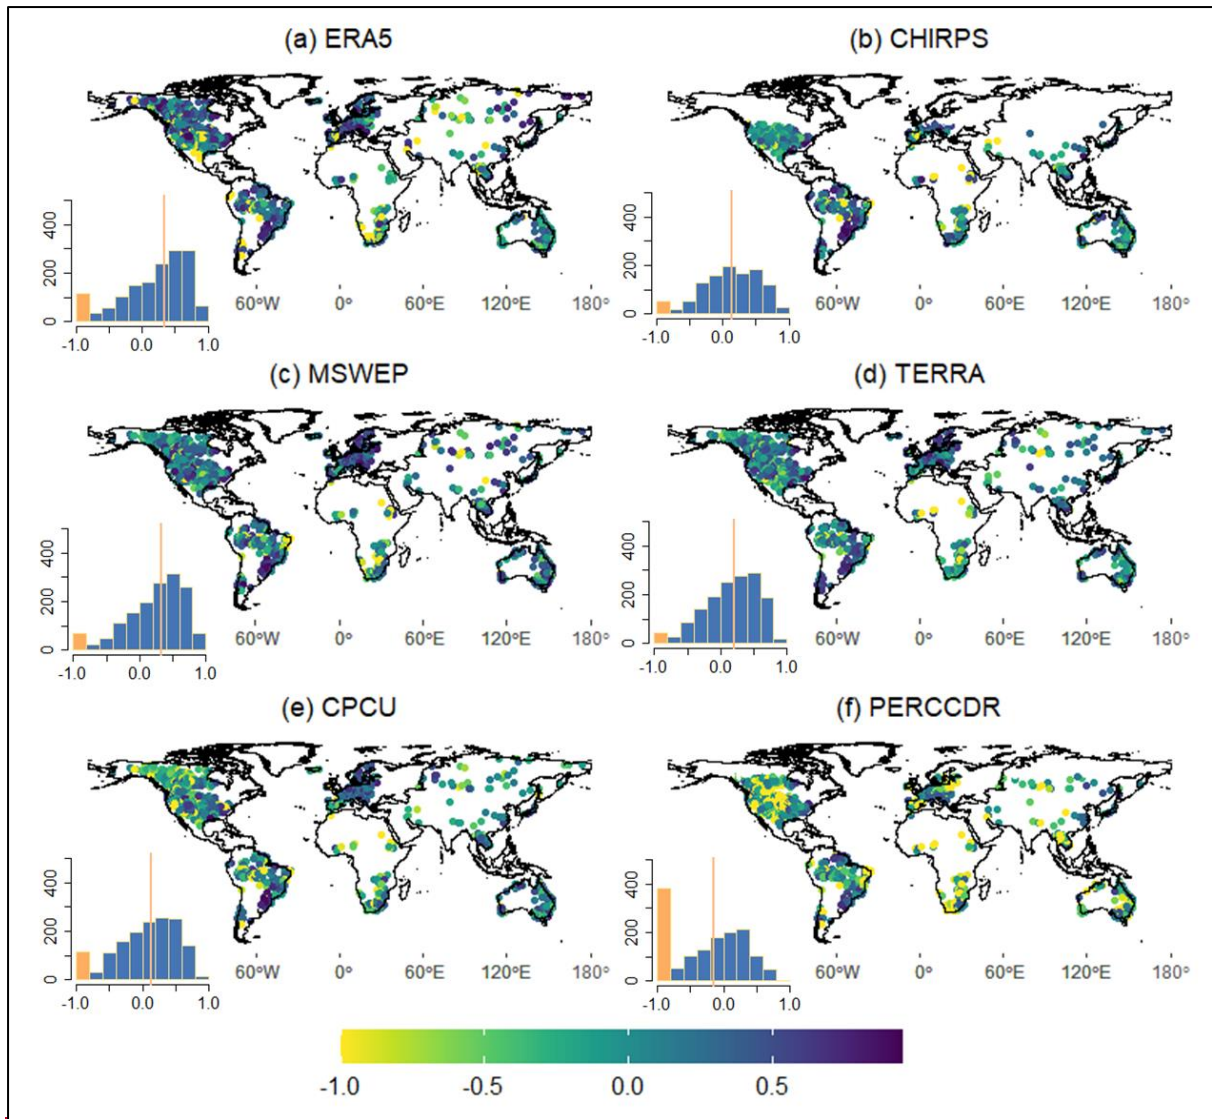

313

314 **Figure 1: Correlation (CC) between annual observed and modelled streamflow data using a) ERA5, b) CHIRPS, c)**  
 315 **MSWEP, d) TERRA, e) CPCU and f) PERCCDR precipitation datasets. The inset histograms show the frequency**  
 316 **distribution (y-axis) of the monthly-annual CC (x-axis), with the yellow-red vertical line indicating the median value.**

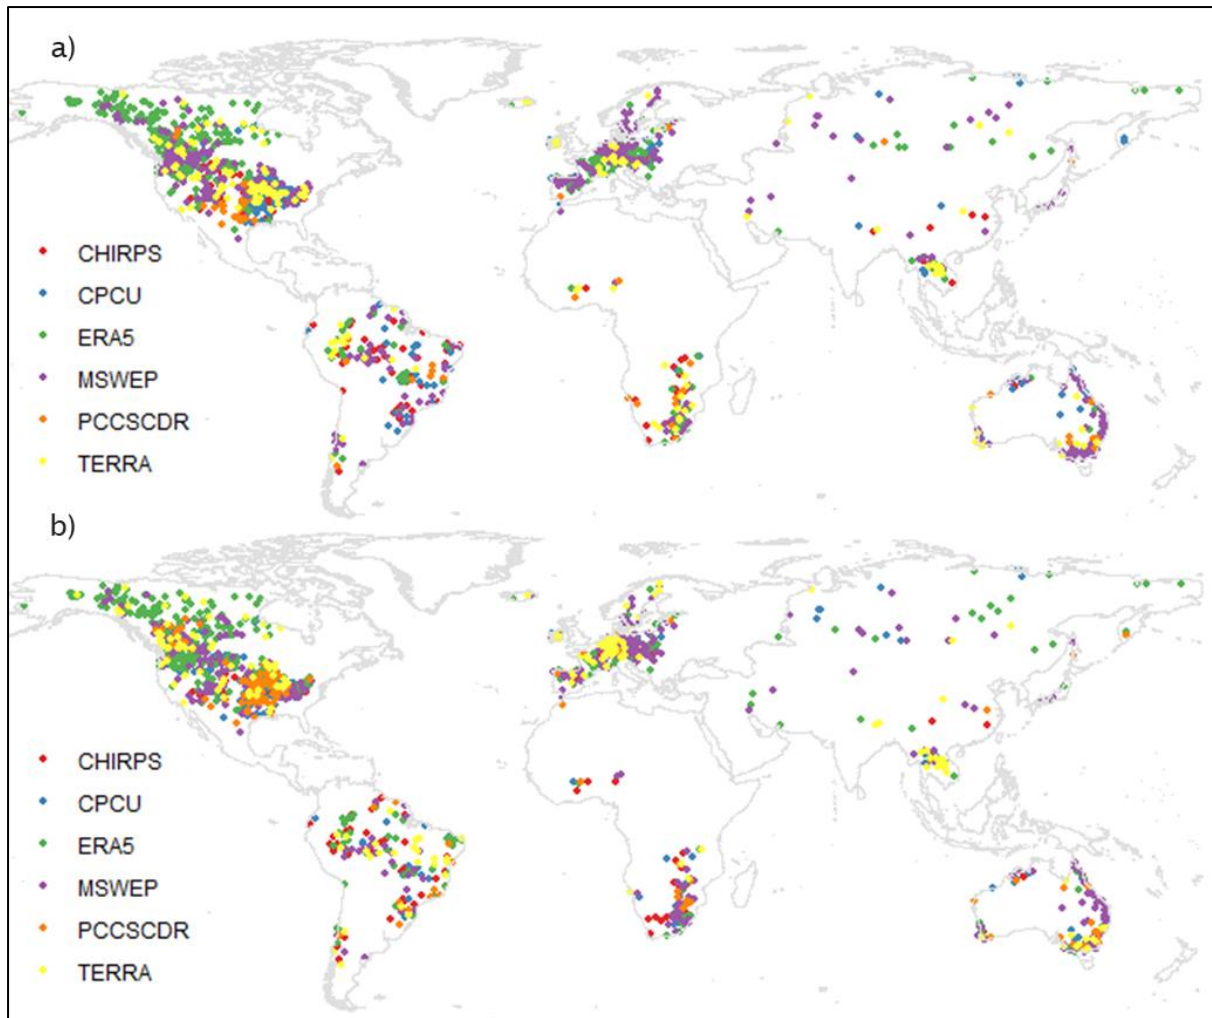

317

319

320 Figure 2: KGE between observed and modelled annual streamflow based on a) ERA5, b) CHIRPS, c) MSWEP, d)  
 321 TERRA, e) CPCU, and f) PERCCDR precipitation datasets. KGE values below -0.41 indicate bad model performance  
 322 than using observed discharge mean as a predictor. The inset histograms show the frequency distribution (y-axis) of  
 323 the monthly-annual KGE (x-axis). KGE values lower than -1 are highlighted in yelloworange. The yellow-red vertical  
 324 line indicates the median value.

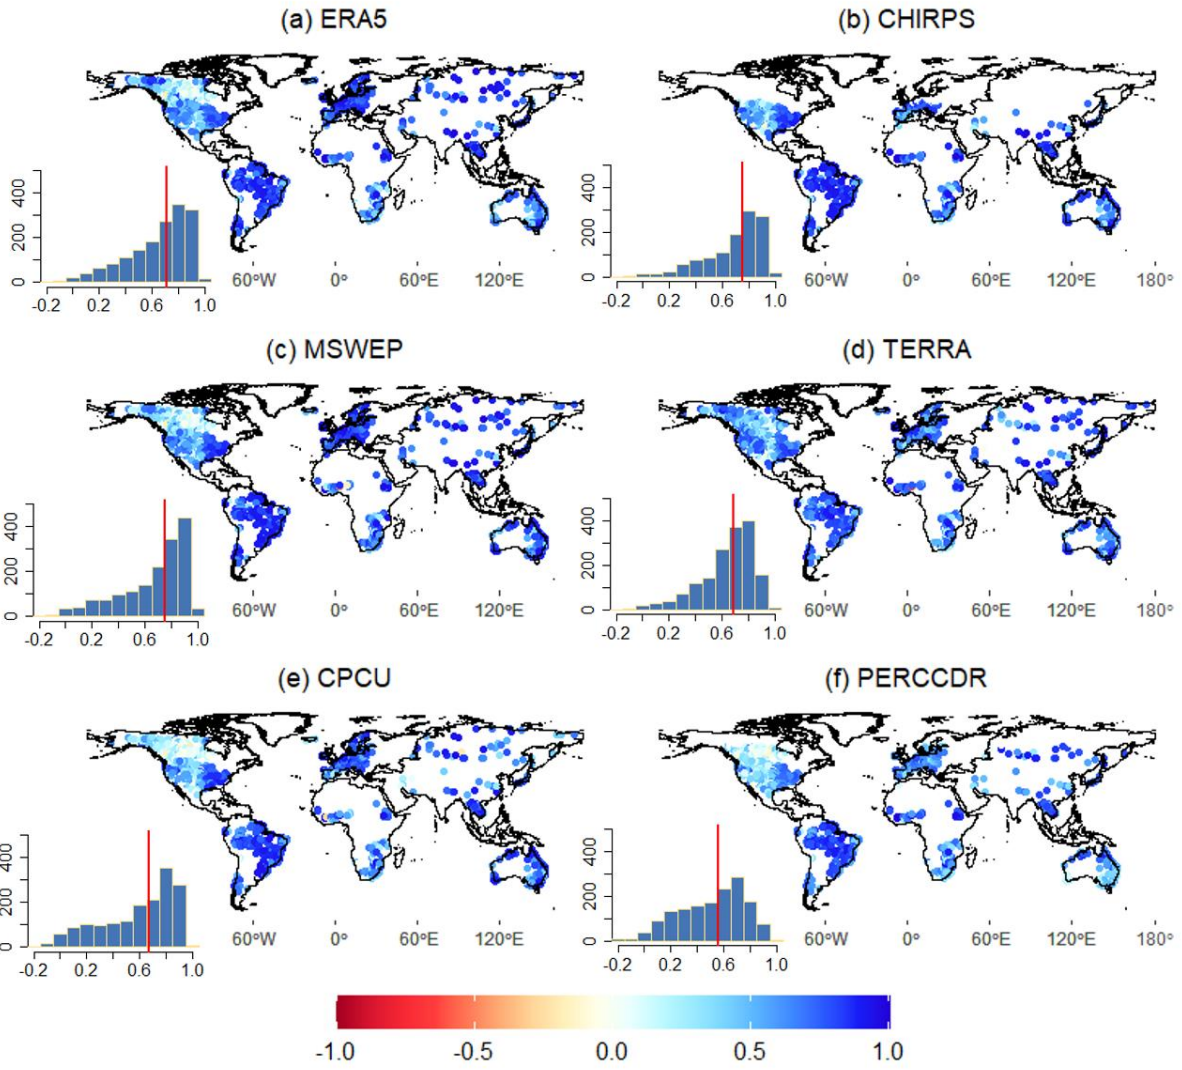

325

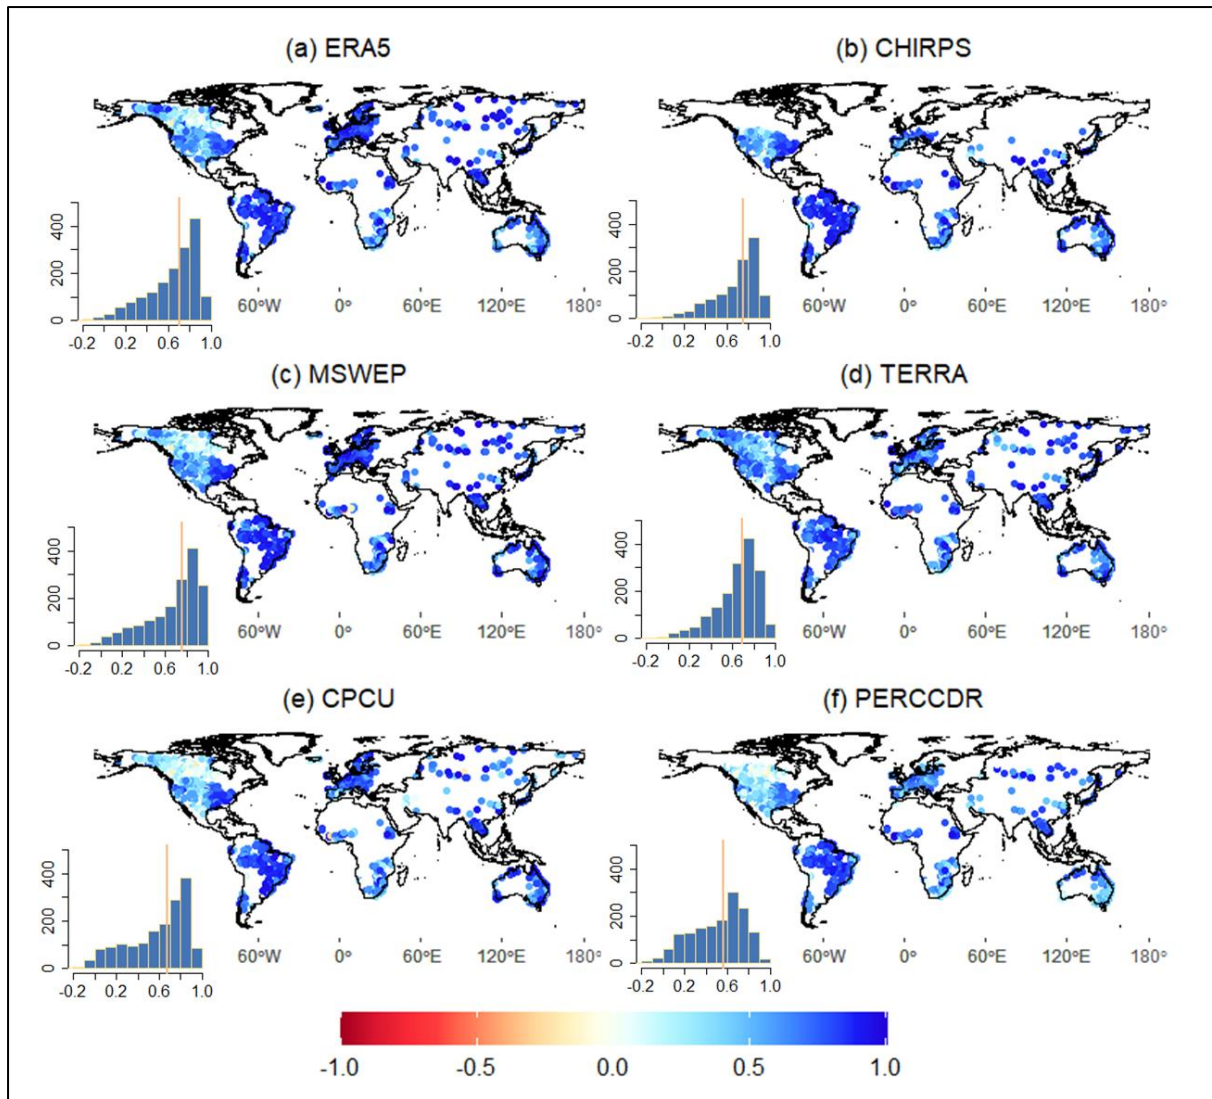

326 **Figure 3: The best performing precipitation dataset (ERA5, CHIRPS, MSWEP, TERRA, CPCU, and PERCCDR) at**  
 327 **each of the observed discharge stations based on annual CC (a) and KGE (b).**

328 **3.2. Performance of the six precipitation datasets for monthly discharge predictions**

329 The six precipitation datasets consistently demonstrate high CC at a monthly scale in large parts of the world,  
 330 except in some rivers of Canada and Australia (Figure 4). The monthly CC, similar to the annual CC, shows a  
 331 relatively better performance of MSWEP with a median CC of 0.76. TERRA is the second-best with a median  
 332 CC of 0.69. MSWEP and TERRA show a higher CC than other datasets in 35% and 28% of the stations,  
 333 respectively. ERA5 and CHIRPS are ranked as the third and fourth datasets with a median CC of 0.71 and 0.75,  
 334 respectively. CPCU and PERCCDR are the least well-performing datasets, which only show the highest CC in  
 335 less than 6% of the stations with a median CC of 0.67 and 0.56, respectively.

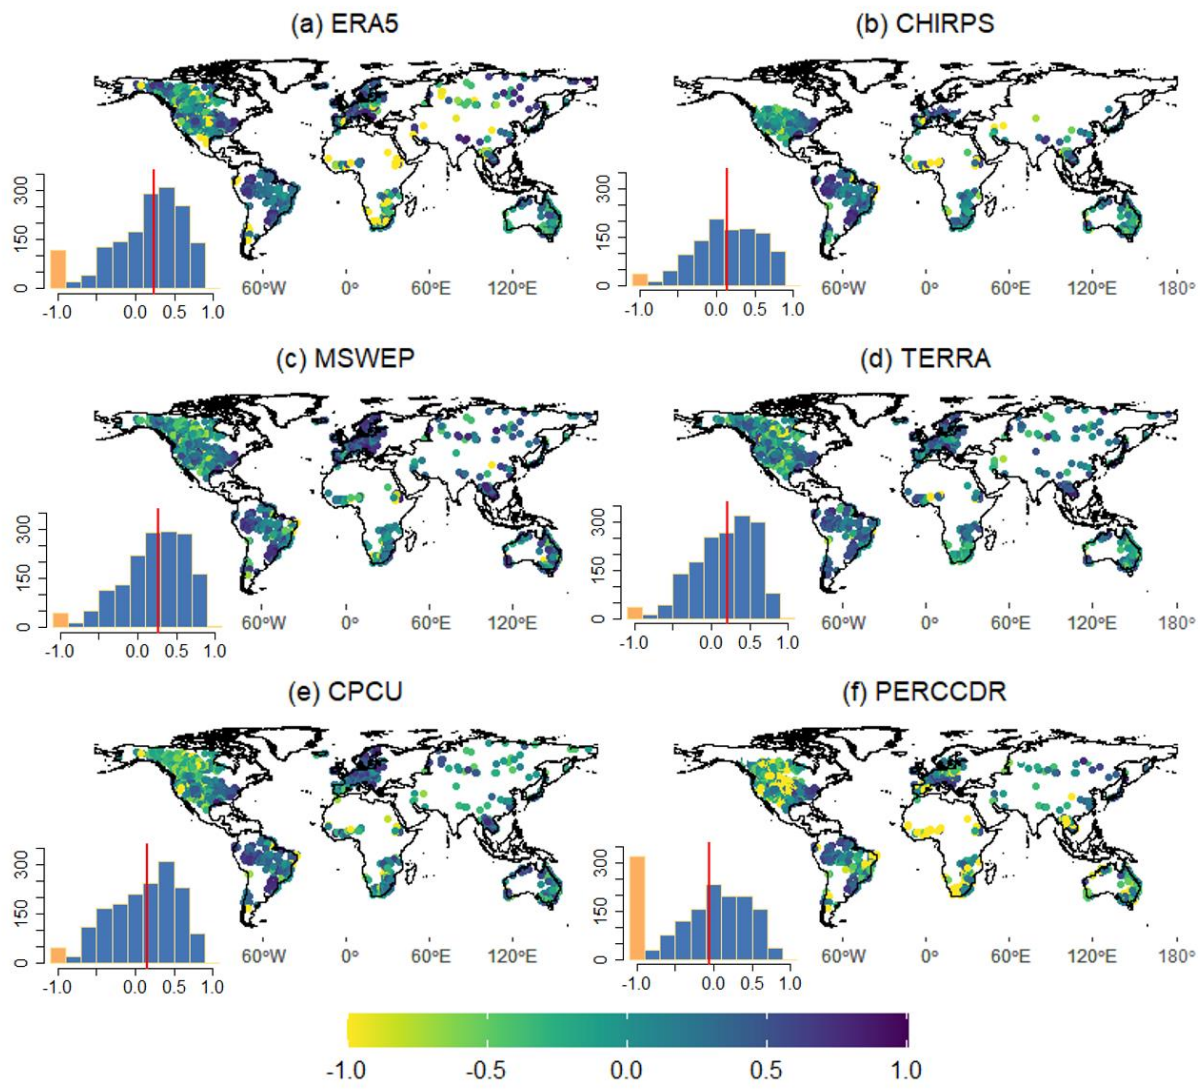

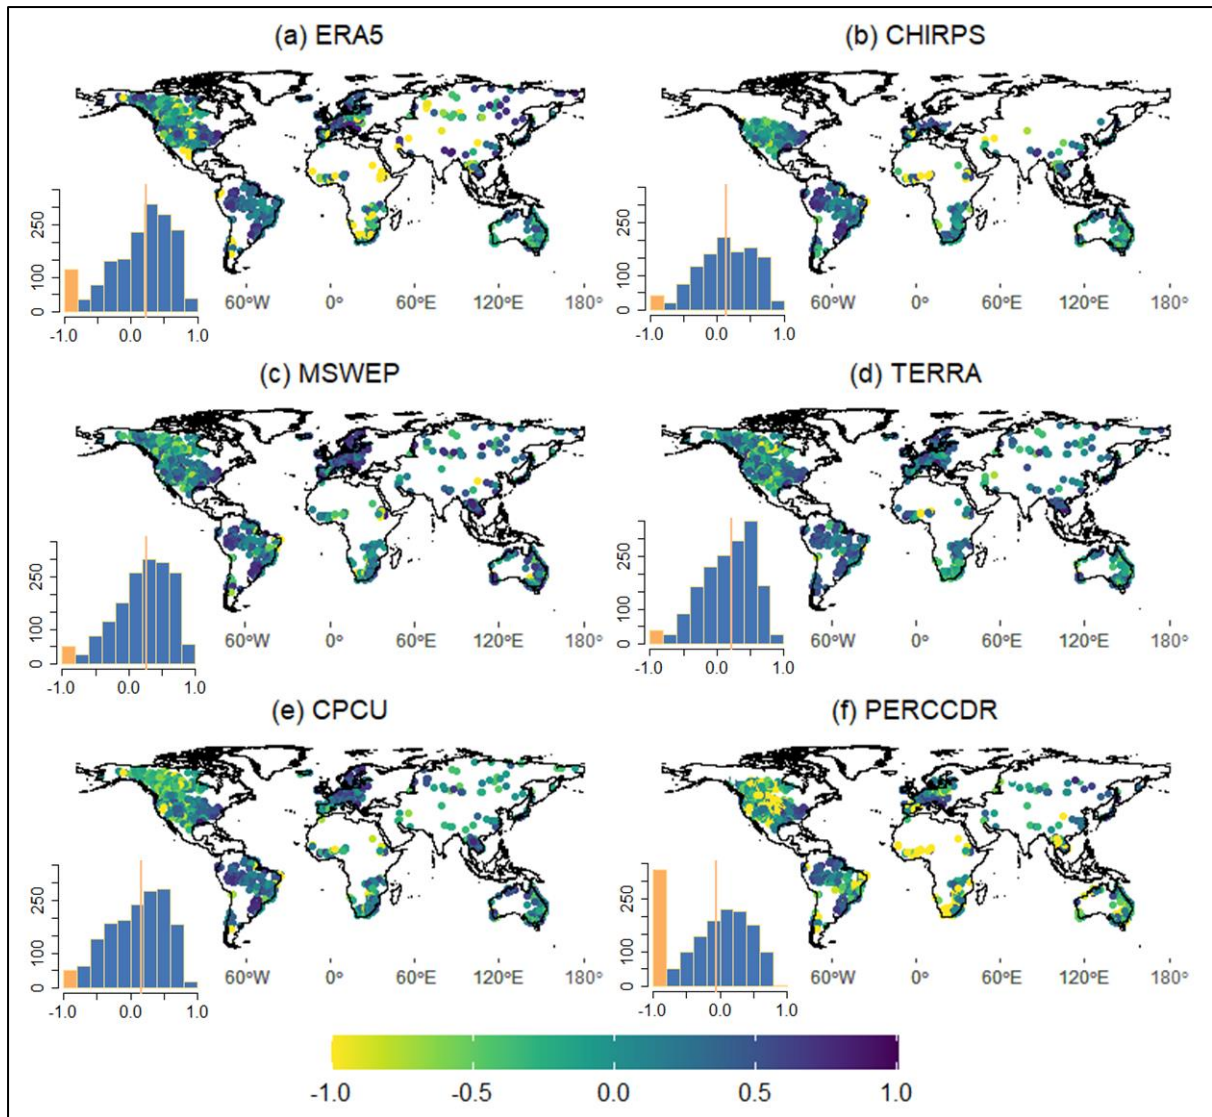

337

338 **Figure 4: Correlation (CC) between monthly observed and modelled streamflow data based on a) ERA5, b) CHIRPS,**  
 339 **c) MSWEP, d) TERRA, e) CPCU and f) PERCCDR precipitation datasets. The inset histograms show the frequency**  
 340 **distribution (y-axis) of the monthly CC (x-axis), with the yellow-red vertical line indicating the median value.**

341 The monthly KGE also indicates the better performance of ERA5 and MSWEP for 26% and 24% of stations,  
 342 respectively (Figure 5). MSWEP showed a lower Pbias and NRMSE than all datasets, except in 5% of the stations  
 343 (Figures S3 and S4). Compared to MSWEP, ERA5 showed a larger Pbias and NRMSE in 15% and 19% of the  
 344 stations. TERRA, a third-best performing dataset based on KGE (18% of stations), shows a lower monthly Pbias  
 345 and RMSE in 85% of the stations compared to CHIRPS, ERA5, and PERCCDR. Compared to all datasets, the  
 346 PERCCDR showed a higher NRMSE and Pbias in 55% and 28% of the stations, respectively. **The spatial**  
 347 **representation of precipitation dataset performance is summarized in Figure S5, highlighting the regions where**  
 348 **individual datasets demonstrate higher monthly CC and KGE values.**

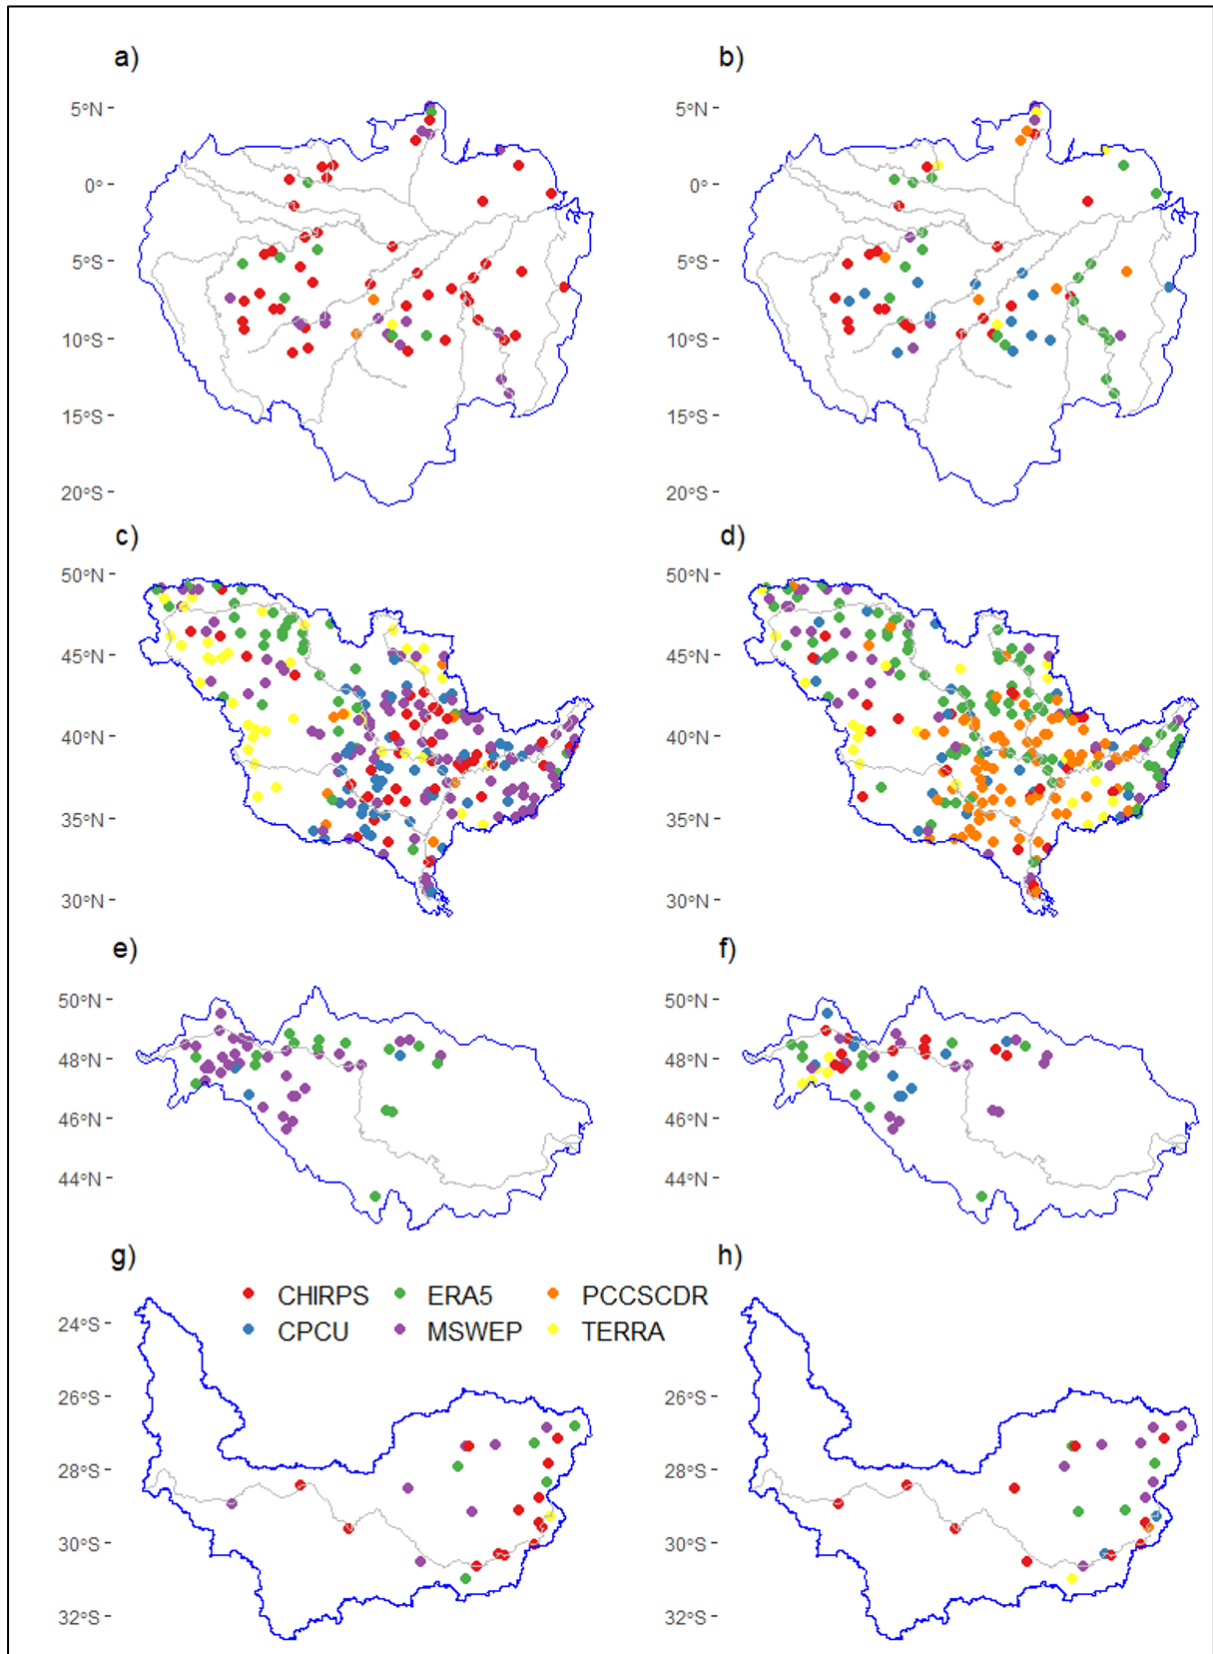

350

351 **Figure 5: Monthly KGE values between observed and modelled streamflow based on a) ERA5, b) CHIRPS, c) MSWEP,**  
 352 **d) TERRA, e) CPCU and f) PERCCDR precipitation datasets. KGE values below -0.41 indicate model performance**  
 353 **that is worse than using the observed discharge mean as a predictor. The inset histograms show the frequency**  
 354 **distribution (y-axis) of the monthly KGE (x-axis). KGE values lower than -1 are highlighted in yelloworange, with the**  
 355 **red vertical line indicating the median value.**

356 The spatial representation of the six precipitation datasets in the Amazon, Mississippi, Danube, and Orange River  
 357 basins is summarised in Figure 6, highlighting the individual datasets exhibiting the highest CC and KGE values  
 358 at each hydrological station. In the Amazon basin, ERA5 (31%) and CHIRPS (29%) emerge as the top performers,  
 359 while PERCCDR (8%) and TERRA (5%) rank lower among the precipitation datasets. In the Mississippi basin,  
 360 MSWEP leads with higher CC in 37% of stations, and ERA5 holds the top products with exhibits higher KGE in  
 361 31% of the stations. Notably, PCCSCDR displays higher KGE values than MSWEP, TERRA, CHIRPS, and  
 362 CPCU in 30% of Mississippi stations. Across the Danube basin, MSWEP outperform the other products with a  
 363 higher CC in 66% of stations and KGE in 30% of the stations, while TERRA and CPCU are the least performing  
 364 products. Furthermore, CHIRPS, in 52% of stations based on CC and 37% based on KGE, outperforming other

365 [datasets in the Orange River basin. In Orange, MSWEP ranks second with higher KGE and CC in about 27% of](#)  
366 [stations, while TERRA and PCCSCDR are the least performing datasets.](#)

367

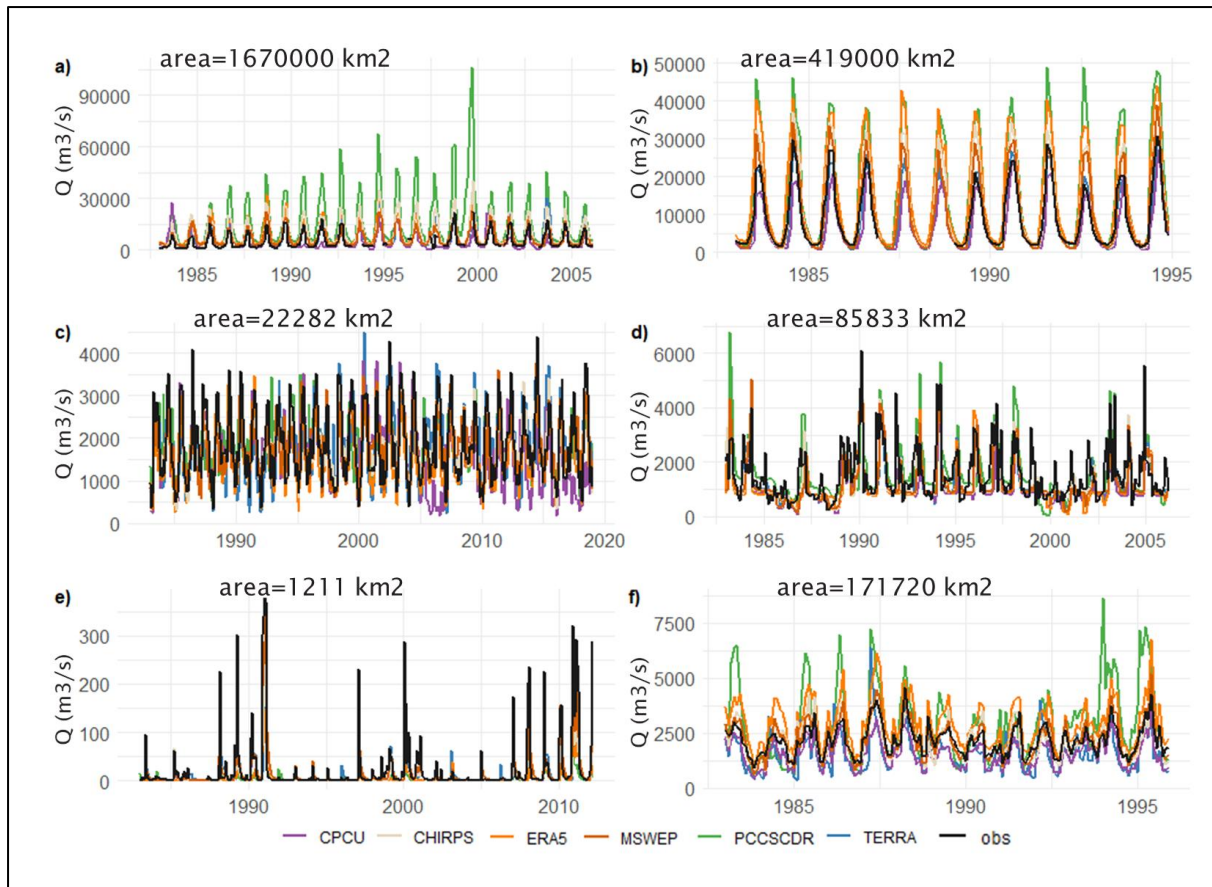

368 Figure 6: Performance of precipitation datasets (ERA5, CHIRPS, MSWEP, TERRA, CPCU, and PERCCDR) at  
 369 discharge stations in a) Amazon, c) Mississippi, e) Danube, and g) Orange river basins based on their monthly CC.  
 370 Performance of the datasets based on KGE for the Amazon, Mississippi, Danube, and Orange River Basins is illustrated  
 371 in figures b, d, f, and h, respectively.

372 ~~Figure 6 shows~~Table 2 summarises the ~~the time series of~~ monthly KGE between observed and modelled  
 373 streamflow, based on the six precipitation datasets, for selected locations in basins of Africa (Niger, Lokoja), Asia  
 374 (Mekong, Khong-Chiam), South America (Amazon, Missao-Icana), North America (Mississippi, Savannah),  
 375 Australia (North East Coast, Mirani-Weir), and Europe (Danube, Dunaalmas). The basins were chosen to  
 376 represent a good-diverse range of climatic regions and drainage areas where there was availability of a long time  
 377 series of observed data (Figure S5). In Niger, the observed monthly flow and variability at Lokoja station are very  
 378 well reproduced by CHIRPS and TERRA with a CC of 0.88 and 0.85, respectively (Figure S5a). Even though  
 379 CPCU showed a lower CC (0.64) at Lokoja, it showed a higher KGE (0.62) and lower Pbias (0.4%) compared to  
 380 the other products. At Lokoja, PERCCDR is the least well-performing dataset with the highest RMSE and Pbias  
 381 and lowest KGE. The monthly variability at the Khong-Chiam station is reproduced by all the precipitation  
 382 products with a CC of greater than 0.91, with MSWEP and TERRA showing the lowest bias and RMSE. ERA5  
 383 and CHIRPS performed well at station Missao-Icana in the Amazon with a CC of 0.9 and RMSE of about 610  
 384 m<sup>3</sup>/s. For stations Savannah, Mirani-Weir, and Dunaalmas, MSWEP is the best product with higher CC (> 0.72)  
 385 and KGE (> 0.62) and lower Pbias and RMSE (Figures S5d - S5f).

386 Table 2. KGE of monthly predictions for selected stations in basins of Africa (Niger), Asia (Mekong), South  
 387 America (Amazon), North America (Mississippi), Australia (North East Coast), and Europe (Danube).

Basin	Stations name	Longitude	Latitude	Catchment area (km <sup>2</sup> )	ERA5	CHIRPS	MSWEP	TERRA	CPCU	PERCCDR
Niger	Lokoja	6.8	7.8	1670000	0.21	-0.1	0.60	0.34	0.62	-0.99
Mekong	Khong Chiam	105.5	15.3	419000	0.13	0.56	0.70	0.91	0.70	-0.04
Amazon	Missao Icana	-67.6	1.1	22282	0.71	0.78	0.73	0.72	0.61	0.65
Mississippi	Savannah	-88.3	35.2	85833	0.59	0.65	0.67	0.66	0.53	0.66
North East Coast	Mirani-Weir	148.8	-21.2	1211	-0.1	0.38	0.62	0.44	0.46	-0.05
Danube	Dunaalmas	18.3	47.7	171720	0.34	0.73	0.78	0.52	0.71	-0.49

388

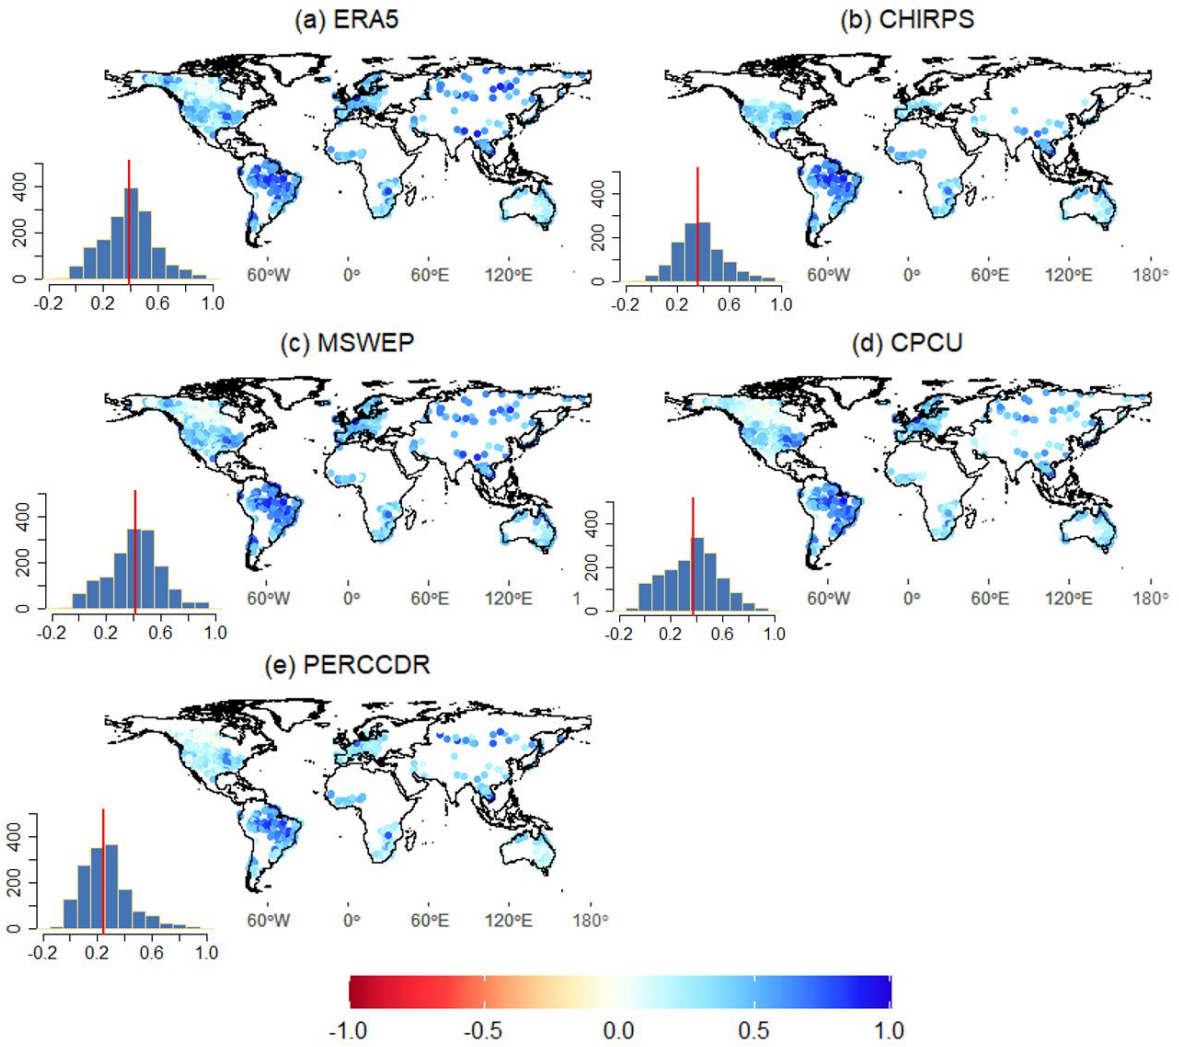

389

390 **Figure 6: Time series of monthly observed (Obs) and modelled streamflow ( $Q$ ;  $m^3/s$ ) based on MSWEP, ERA5,**  
 391 **CHIRPS, CPCU, TERRA, and PERCCDR precipitation datasets for locations in river basins of a) Niger (Lokoja), b)**  
 392 **Mekong (Khong-Chiam), c) Amazon (Missao-Icana), d) Mississippi (Savannah), e) North East Coast (Mirani-Weir),**  
 393 **and f) Danube (Dunaalmas).**

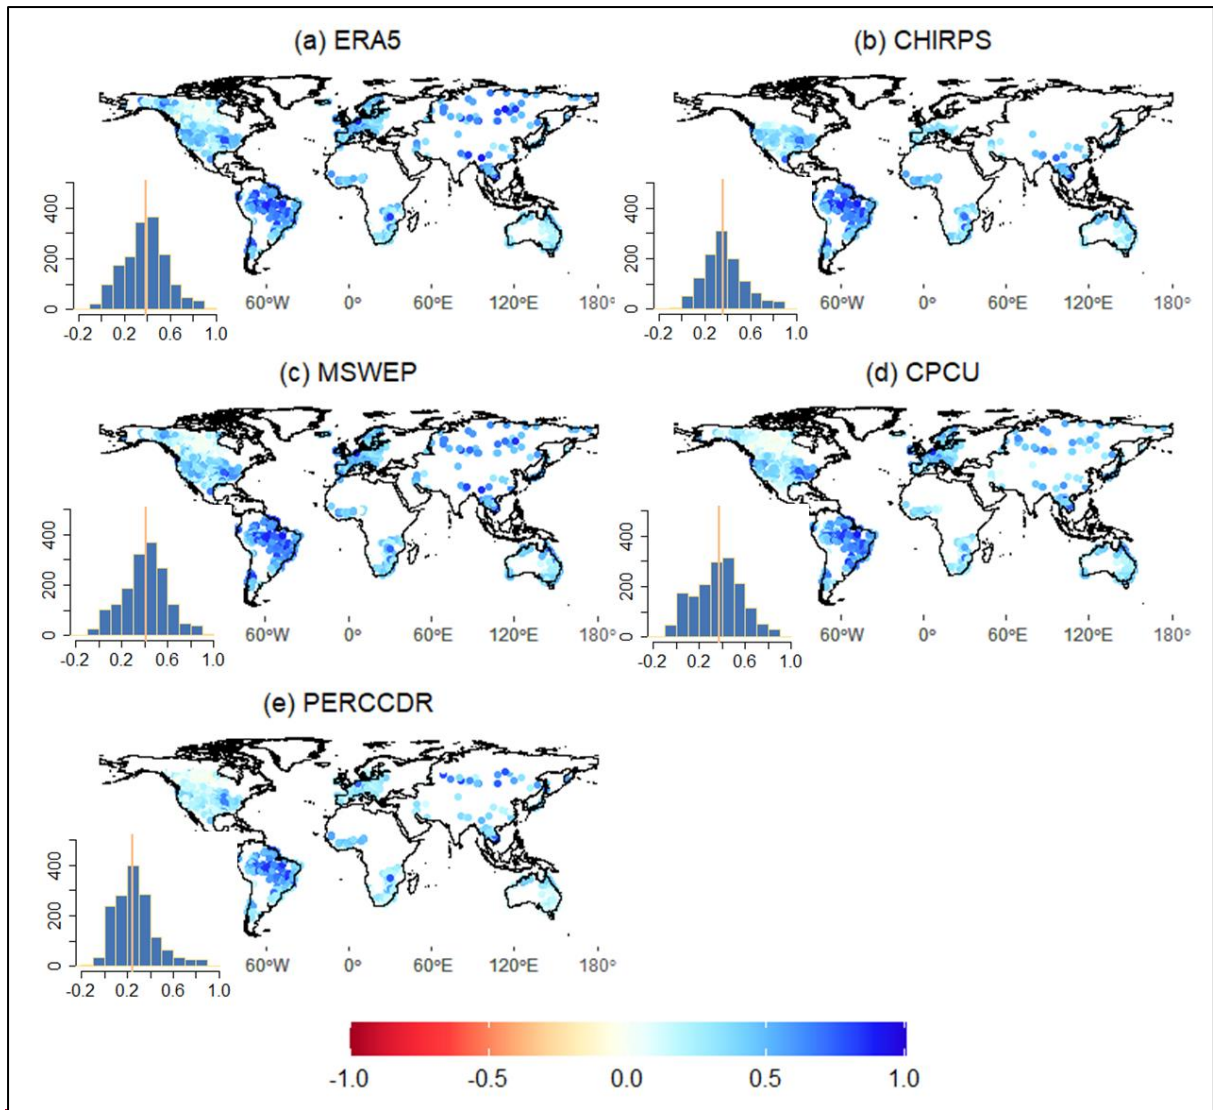

394 **3.3. Performance of the precipitation datasets for daily and daily extreme discharge predictions**

395 Based on the daily evaluation, MSWEP followed by ERA5 show a higher CC in more than 50% of the stations  
 396 with median values of 0.41 and 0.39, respectively (Figure 7). ERA5 and MSWEP performed well in 31% and  
 397 31% of the stations with high KGE values (Figure 8). Similar to the monthly evaluation, PERCCDR shows poorer  
 398 performance (lower CC and KGE, higher biases and errors) in almost 95% of the stations. Even though ERA5  
 399 showed a higher CC and KGE in 30% of the stations it shows a higher NRMSE (up to 250%) and Pbias (up to  
 400 100%) in 20% and 30% of the stations (Figures S6 and S7). Overall, MSWEP and CHIRPS showed lower NRMSE  
 401 and Pbias compared to the other products. The CC and KGE of all the products (except CHIRPS) are lower in  
 402 North America compared to stations in South America, Europe, and Australia. The spatial representation of  
 403 precipitation dataset performance, highlighting the individual datasets exhibiting the highest daily CC and KGE  
 404 values at each observation point, is provided in Figure S9. Additionally, Figure S10 depicts the spatial  
 405 representation of each precipitation dataset for the Amazon, Mississippi, Danube, and Orange River Basins. In  
 406 the Mississippi basin, ERA5 exhibited the highest KGE and CC values, followed by MSWEP and CPCU (Figure  
 407 S10). In the Amazon basin, ERA5 and CHIRPS displayed the highest KGE and CC values compared to the other  
 408 datasets. For the Danube basin, CPCU followed by MSWEP emerged as the best precipitation product relative to

409 ERA5, PCCSCDR, and CHIRPS. In the Orange River Basin, MSWEP based on CC and CHIRPS based on KGE  
410 were the top-performing products, while PCCSCDR performed the least.

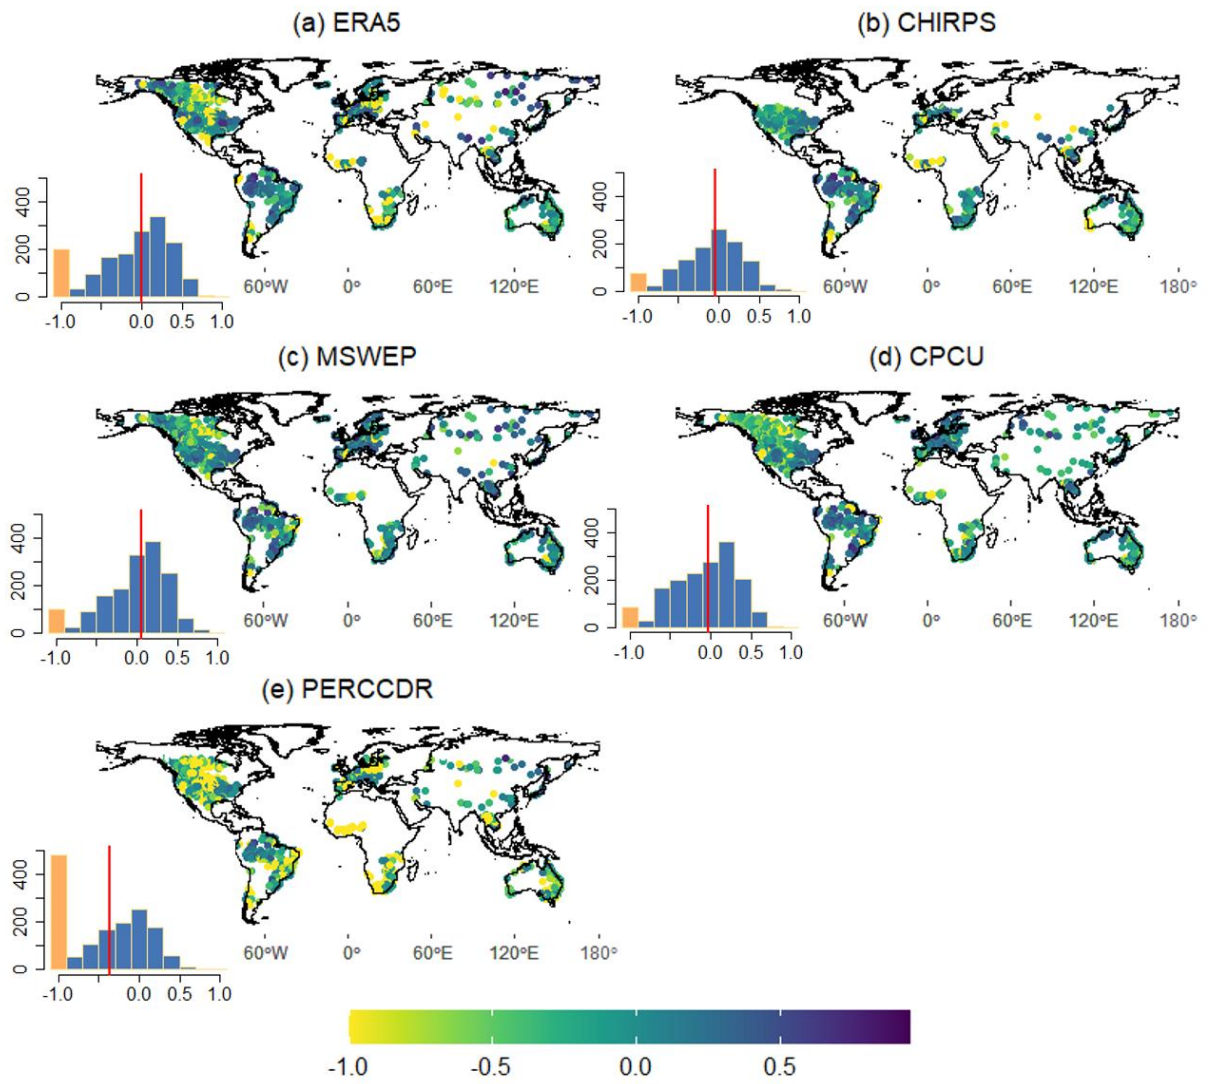

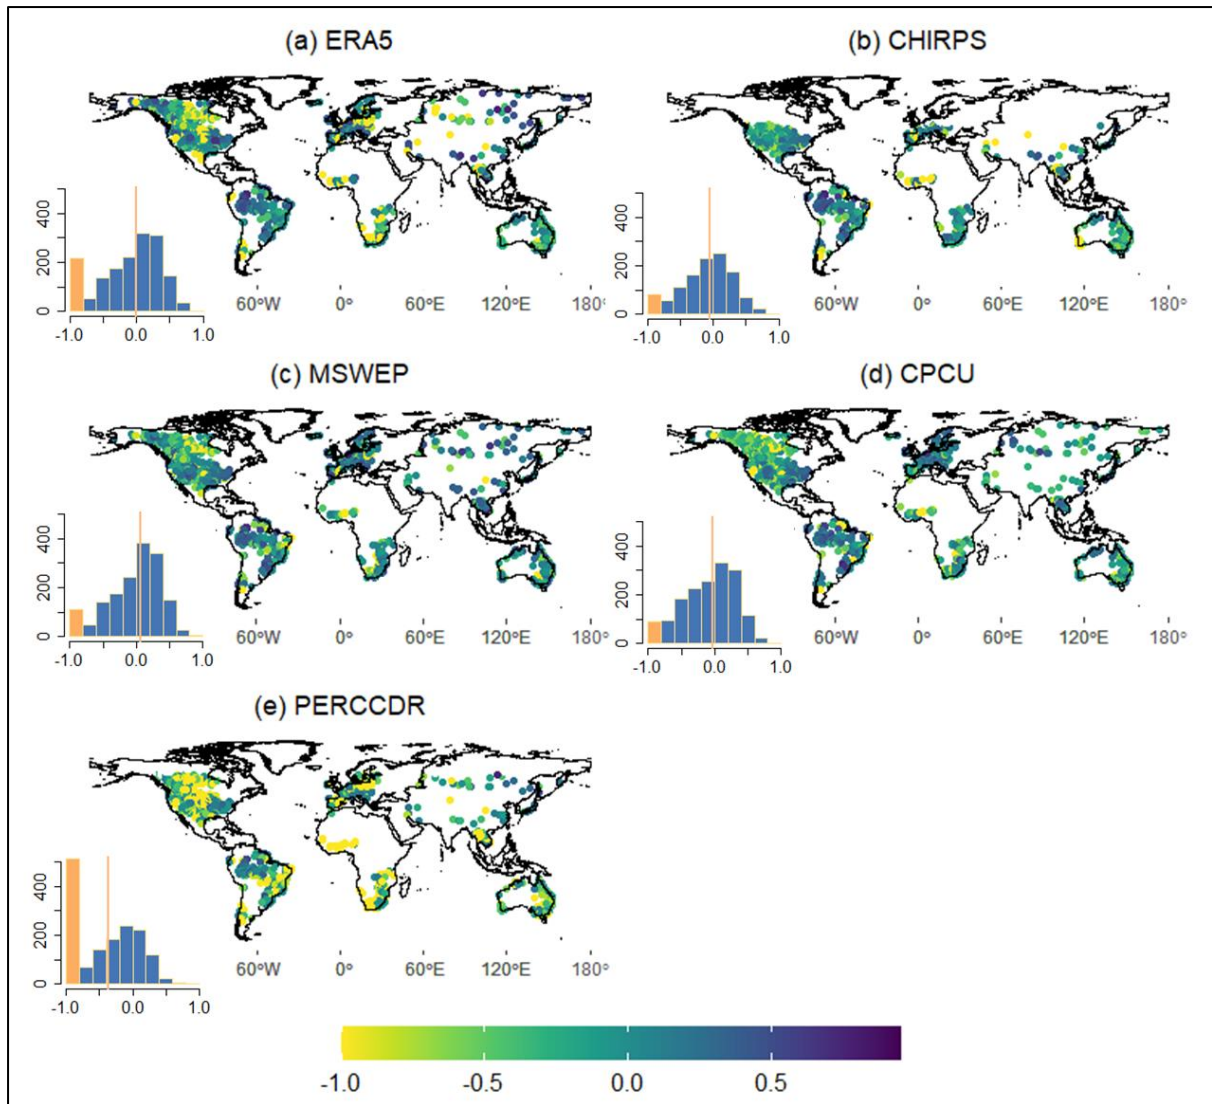

412

413 Figure 7: Correlation (CC) between daily observed and modelled streamflow data using a) ERA5, b) CHIRPS, c)  
 414 MSWEP, d) CPCU and e) PERCCDR precipitation datasets. The inset histograms show the frequency distribution (y-  
 415 axis) of the daily CC (x-axis), with the yellow-red vertical line indicating the median value.

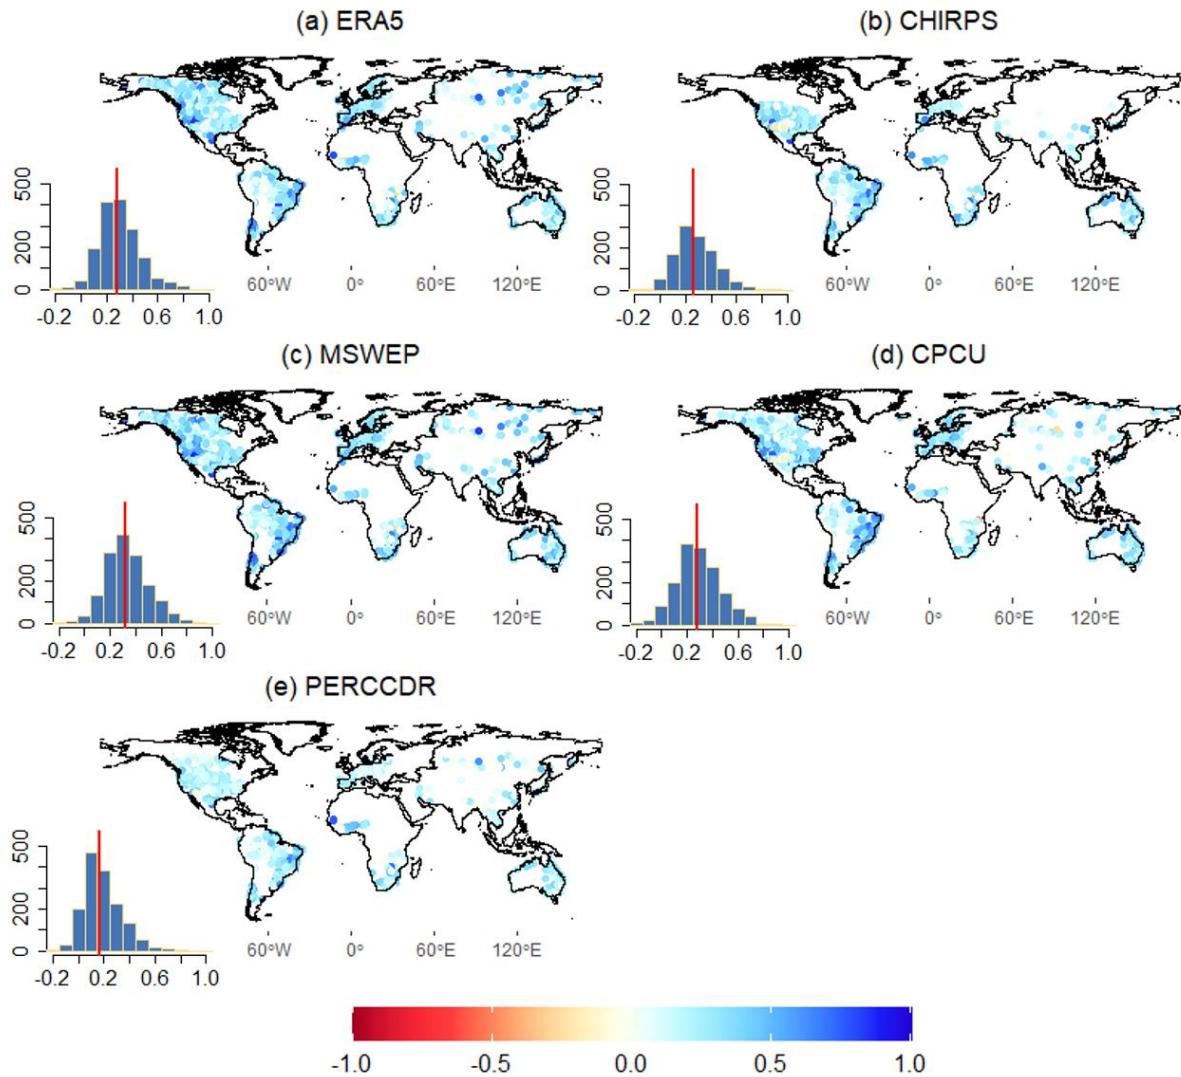

417

418 **Figure 8: Daily KGE values between observed and modelled streamflow based on a) ERA5, b) CHIRPS, c) MSWEP,**  
 419 **d) CPCU, and e) PERCCDR precipitation datasets. KGE values below -0.41 indicate bad model performance than**  
 420 **using observed discharge mean as a predictor. The inset histograms show the frequency distribution (v-axis) of the**  
 421 **daily KGE (v-axis). KGE values lower than -1 are highlighted in yelloworange, with the yellow-red vertical line**  
 422 **indicates-indicating the median value.**

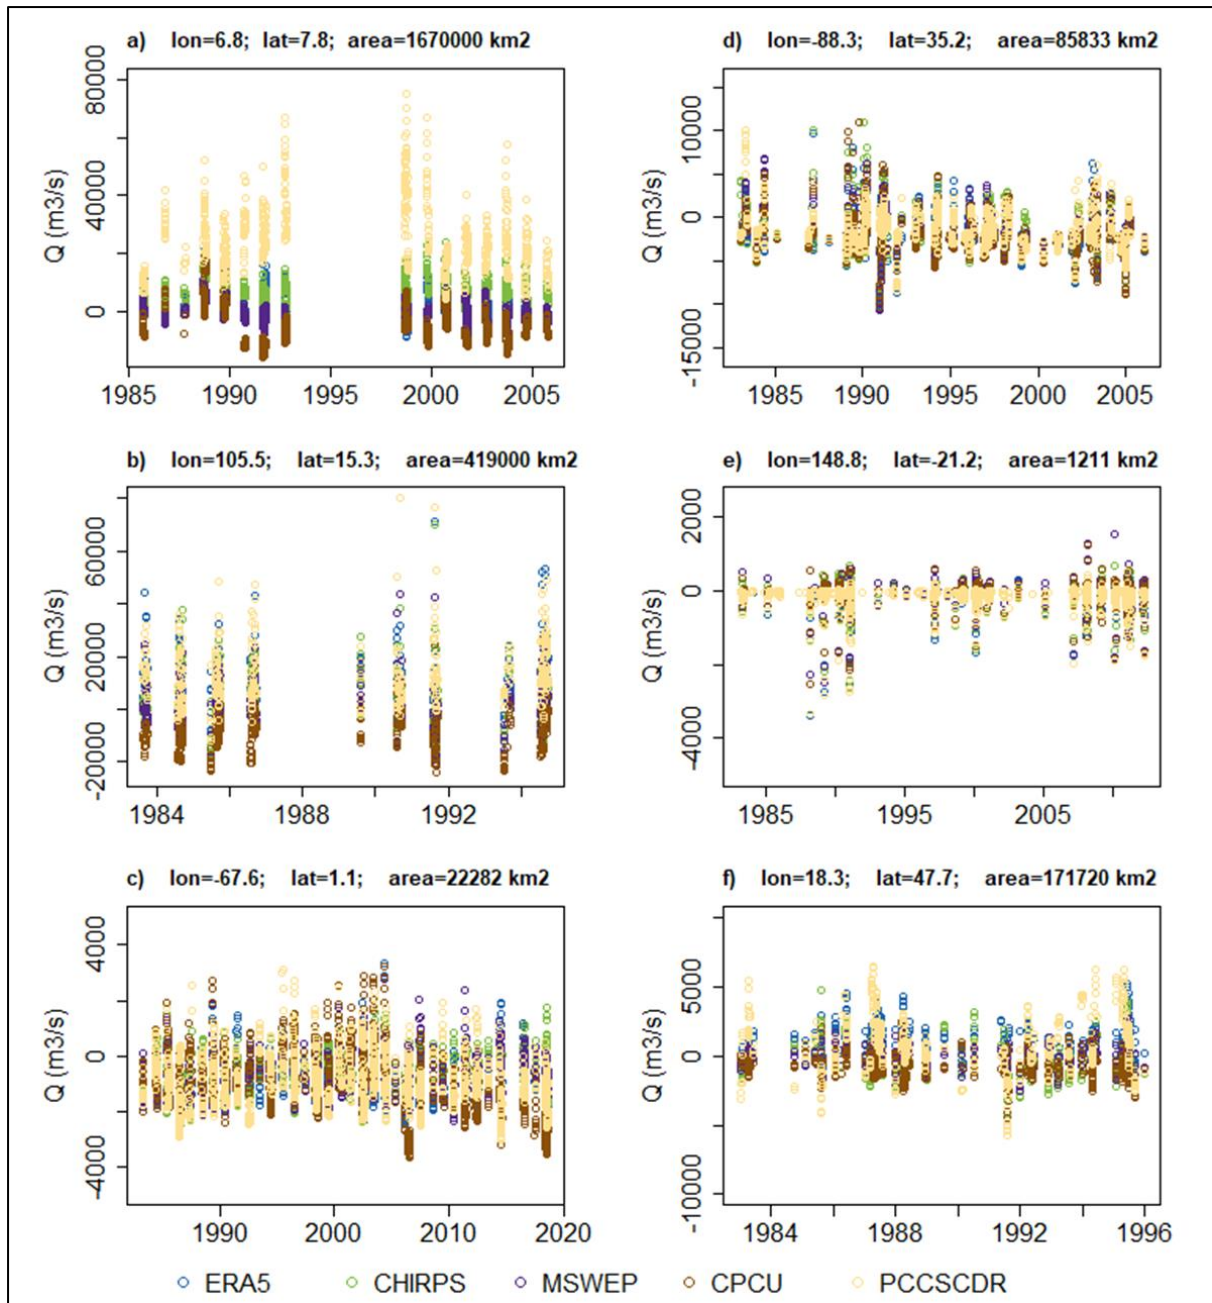

423 The performance of the daily precipitation products is also assessed for daily extremes in terms of the Q10 and  
 424 Q90 values. Based on the CC, MSWEP is the best-performing dataset for Q10 (Figure 9) and Q90 (Figure S8),  
 425 and Q10 (Figure S9). For Q10, MSWEP and CPCU exhibited a higher CC than other datasets at 38% and 32% of  
 426 the stations, respectively. Similarly, for Q90, MSWEP and ERA demonstrated a higher CC compared to other  
 427 datasets at 35% and 30% of the stations. The median CC for Q10 (Q90) is 0.32 (0.41), 0.28 (0.36), 0.27 (0.35),  
 428 0.26 (0.38), and 0.16 (0.23) for MSWEP, CPCU, CHIRPS, ERA5, CHIRPS, and PERCCDR, respectively. Similar  
 429 to the annual, monthly and daily evaluations, PERCCDR showed poor performance for the two extremes (Q90  
 430 and Q10). Overall, the performance of the datasets is lower for extremes compared to the annual, monthly and  
 431 daily scales.

432

433 **Figure 9: Correlation (CC) between observed and modelled daily extremes (Q10, high flow) streamflow data a) ERA5,**  
 434 **b) CHIRPS, c) MSWEP, d) CPCU and e) PERCCDR precipitation datasets. The inset histograms show the frequency**  
 435 **distribution (y-axis) of the daily Q10 CC (x-axis), with the red vertical line indicating the median value.**

436 Figure 9 displays differences between the observed and modelled Q10 for selected stations of Lokoja, Khong-  
 437 Chiam, Missao Ieana, Savannah, Mirani Weir, and Dunaalmas (Table 2). Compared to ERA5, CPCU, and  
 438 PERCCDR, MSWEP followed by CHIRPS showed a higher CC (0.21-0.62) and lower Pbias and RMSE in all  
 439 stations. At stations Missao Ieana, Savannah, and Mirani Weir, the observed Q10 is underestimated with a Pbias  
 440 of between -20% to -80%. In all the stations, the positive and negative bias is large in PERCCDR and CPCU  
 441 datasets.

442

443 **Figure 9: The difference in Q10 (high flow) between observed and modelled streamflow based MSWEP, CHIRPS,**  
 444 **ERA5, CPCU, and PERCCDR at selected locations (Table 2) in river basins of a) Niger (Lokoja), b) Mekong (Khong-**  
 445 **Chiam), c) Amazon (Missao-Ieana), d) Mississippi (Savannah), e) North-East Coast (Mirani-Weir), and f) Danube**  
 446 **(Dunaalmas).**

447 **4. Discussion and Conclusion**

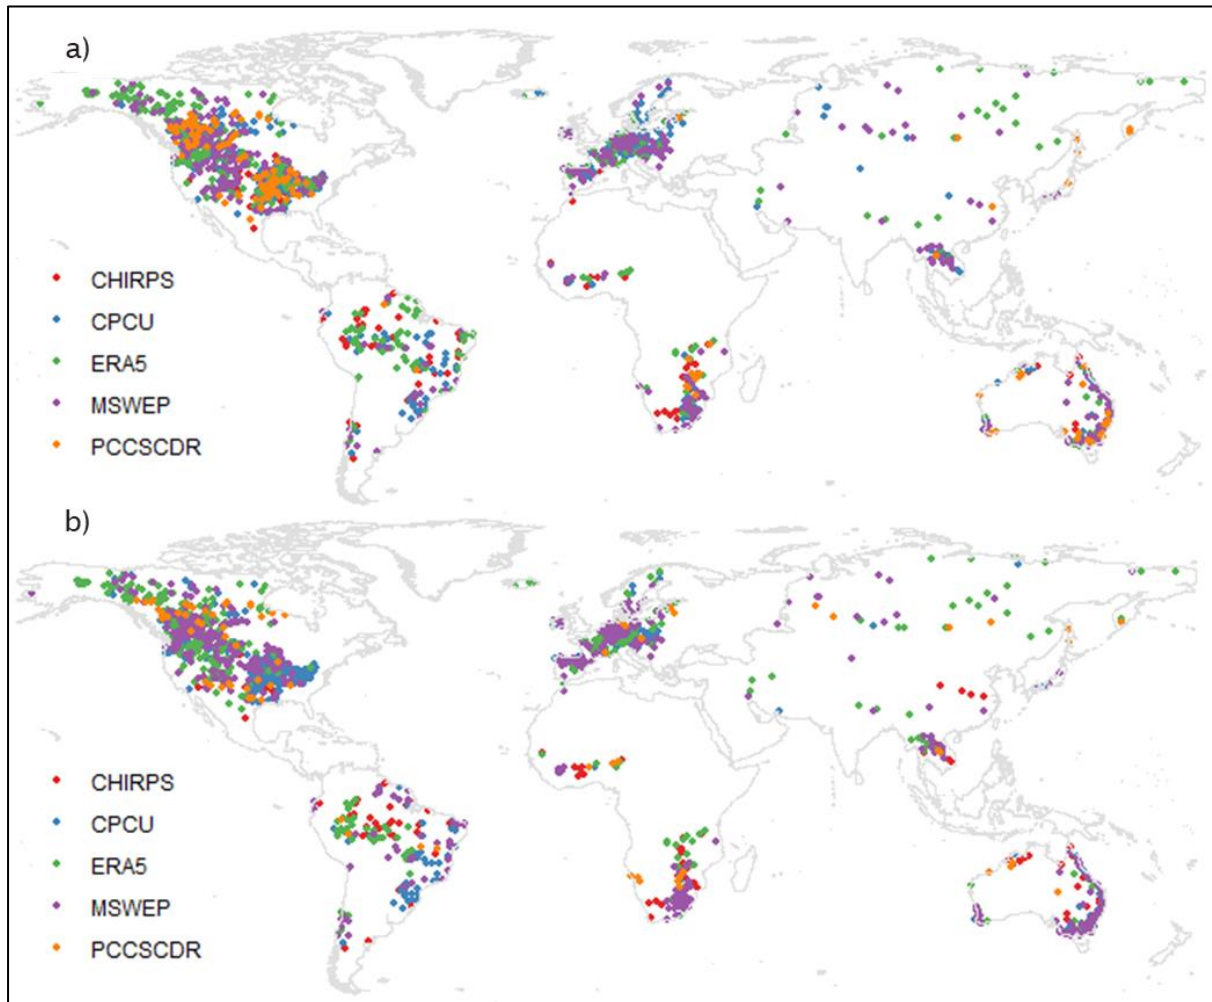

448 **Given the challenges in representing precipitation at global scales, satellite, climate model, and reanalysis based**  
 449 **precipitation datasets can form the basis for monitoring and prediction of water resources and hydrological**  
 450 **extremes, particularly in data scarce regions of the world (Sheffield et al., 2018; Dembélé et al., 2020).**  
 451 **Nevertheless, uncertainties and errors in these datasets require careful analysis to assess their suitability for a**

452 ~~specific use. Error in satellite-based precipitation estimates can be due to errors in the sensor measurements, the~~  
453 ~~frequency of sampling, and the retrieval algorithms, including the representation of cloud physics (Dembélé et al.,~~  
454 ~~2020; Laiti et al., 2018; Alazzy et al., 2017). Climate model-based datasets, including reanalyses, have large~~  
455 ~~uncertainty due to their coarse spatial resolution and ambiguity associated with model parameters (Gebrechorkos~~  
456 ~~et al., 2018; AL-Falahi et al., 2020; Dembélé et al., 2020; Her et al., 2019). Reanalysis datasets may correct for~~  
457 ~~some of these errors via the assimilation of observational data, but this comes with its own uncertainties due to~~  
458 ~~the error characteristics of the assimilated observations and the assimilation scheme (Sheffield et al., 2006; Parker,~~  
459 ~~2016). In hydrological modelling, errors and biases in precipitation data result in poor representation of the~~  
460 ~~hydrological responses and affect applications (Maggioni and Massari, 2018; Zambrano-Bigiarini et al., 2016).~~  
461 ~~For example, according to Bárdossy et al. (2022), uncertainty in precipitation can lead to hydrological model~~  
462 ~~errors of up to 50%. Hence, it is important to assess the quality and accuracy of the precipitation products before~~  
463 ~~using them in global or basin-scale hydrological models. In data-limited regions, hydrological models driven by~~  
464 ~~precipitation datasets developed from satellite sources, reanalysis or climate models are the only plausible way to~~  
465 ~~represent the terrestrial water cycle (van Huijgevoort et al., 2013).~~

466 ~~In light of the above, this study assesses the performance of selected global and quasi-global precipitation datasets~~  
467 ~~for global hydrological modelling. It is important to note that this study assesses the precipitation datasets without~~  
468 ~~calibration of the WBMsed model for each dataset, which could theoretically improve their performance in~~  
469 ~~replicating observed river discharge. Within this context, our objective is not to evaluate the absolute performance~~  
470 ~~of the hydrological model, which can be influenced by local factors, rather our focus is on comparing the relative~~  
471 ~~performance of these datasets at individual locations across various precipitation datasets. Based on the evaluation~~  
472 ~~at annual, monthly and daily time scales and analysis of daily extremes, no single precipitation dataset consistently~~  
473 ~~exhibits high accuracy across all geographical regions, nor doesis one consistently better outperform than the other~~  
474 ~~datasets. This finding is in line-agreement with previous studies (Beck et al., 2017a; Dembélé et al., 2020). A~~  
475 ~~similar pattern of varied performance (e.g., lower in Africa and the central United States and better in Europe) by~~  
476 ~~different global hydrological models and precipitation datasets has been presented (Beck et al., 2017a; Lin et al.,~~  
477 ~~2019; Harrigan et al., 2020). In addition to the uncertainty in the precipitation datasets, the poorer performance in~~  
478 ~~some regions presented in this and previous studies (Beck et al., 2017a; Lin et al., 2019; Harrigan et al., 2020) can~~  
479 ~~be due exacerbated by the lack of representation in the hydrological models of anthropogenic influences, such~~  
480 ~~as for agriculture, irrigation, water supply, and energy production.~~

481 Comparably, MSWEP and ERA5 consistently exhibited higher CC and KGE values at over 50% of the stations  
482 across annual, monthly, and daily time scales. According to Gu et al. (2023), satellite- and reanalysis-based  
483 precipitation datasets, such as MSWEP and ERA5, can provide satisfactory performance for simulating discharge  
484 globally. The higher performance of MSWEP indicates the advantage of incorporating a large number of daily  
485 observations from field-based meteorological stations, in addition to a large set of satellite and reanalysis datasets  
486 (Beck et al., 2017a, 2019a). Other studies have also shown the good performance of MSWEP for hydrological  
487 modelling in different parts of the world (Beck et al., 2017a; Lakew, 2020; Li et al., 2022a; Reis et al., 2022; Gu  
488 et al., 2023; López López et al., 2017; Satgé et al., 2019; Ibrahim et al., 2022). For example, Satgé et al. (2019)  
489 evaluated 12 satellite-based precipitation estimates such as MSWEP, CHIRPS and PERSIANN-CDR in South  
490 America (Lake Titicaca region) and found MSWEP was the best precipitation dataset for realistic simulation of

491 river discharge. MSWEP was also found to be the most reliable precipitation dataset compared to multiple datasets  
492 such as CHIRPS and CMORPH for hydrological and climate studies in basins of Eastern China (Shaowei et al.,  
493 2022; Wu et al., 2018). ~~Figure 10 displays the datasets with higher CC and KGE values for modelling daily~~  
494 ~~discharge, offering a clear depiction of the spatial variability in precipitation dataset performance.~~

495  
496 ~~Figure 10: The best performing precipitation dataset (CHIRPS, CPCU, ERA5, MSWEP, and PERCCDR) at each of~~  
497 ~~the observed discharge stations based on daily CC (a) and KGE (b).~~

498 Even though ERA5 showed a higher KGE and CC than MSWEP, CHIRPS and TERRA in about 32% of the  
499 stations it showed a higher error and biases. Previous studies have revealed bias and errors in ERA5 precipitation  
500 (Lavers et al., 2021; Bechtold et al., 2020; AL-Falahi et al., 2020; Jiang et al., 2023; Lavers et al., 2022), which  
501 leads to propagated errors and bias in hydrological modelling outputs. Harrigan et al. (2020) also reported large  
502 biases in ERA5-driven hydrological simulations in the Central United States, South America (e.g., Brazil), and  
503 Africa. According to Lavers et al. (2022), ERA5 precipitation is more reliable in extratropical areas compared to  
504 tropical areas. Despite CPCU being a gauge-based precipitation dataset, it did not show as good performance as  
505 MSWEP and ERA5 on annual, monthly, and daily timescales. In addition to the lower KGE and CC, CPCU  
506 showed higher bias and error, particularly on annual and monthly time scales. The bias and errors in CPCU can  
507 be due to the coarse resolution (0.5°) and the limited number of stations used to develop the datasets, particularly

508 in Africa and South America. According to Beck et al. (2017a), CPCU can be used in large river basins with dense  
509 meteorological stations but can be disadvantageous in Africa and South America. This highlights the need to  
510 expand and maintain the meteorological stations in these regions, but also the need to draw from satellite and  
511 model data sources. The PERSIANN-CDR is the least-performing product with lower KGE and higher errors and  
512 biases, which has been highlighted elsewhere in terms of its inability to represent precipitation extremes (Miao et  
513 al., 2015; Solakian et al., 2020).

514 The precipitation datasets show limited skill overall in reproducing daily extremes (high and low flows), relative  
515 to the annual and monthly time scales. MSWEP and CPCU have shown a high CC in about 38% of the stations.  
516 This is consistent with the findings of Tang et al., (2019) for the Mekong River Basin. CHIRPS and PERSIANN-  
517 CDR are the least skilful in capturing extremes with a very low CC and large positive and negative biases (Araujo  
518 Palharini et al., 2021). For instance, numerous precipitation products have been observed to both underestimate  
519 and overestimate low and high precipitation values in Brazil (Palharini et al., 2020), consequently resulting in  
520 corresponding underestimations and overestimations of low and high streamflows. In general, several studies have  
521 concluded that precipitation datasets exhibit a substantial disparity in daily extreme precipitation events (e.g.,  
522 Araujo Palharini et al., 2021; Jiang et al., 2019; Huang et al., 2022), which can be attributed to factors such as  
523 inaccuracies in satellite sensors, retrieval algorithms, temporal sampling, and satellite-observation merging and  
524 bias correction procedures used, particularly in gauge-limited regions (Miao et al., 2015; El Kenawy et al., 2015;  
525 Shen et al., 2010; Jiang et al., 2019). In addition to the uncertainty of the precipitation datasets, the limited  
526 availability of hydrological observations limits the ability to assess these datasets globally, especially for extreme  
527 flood and drought events (Brunner et al., 2021).

528 ~~While our study evaluates six global precipitation datasets for hydrological modelling using~~ Whilst the WBMsed  
529 ~~model has been shown to perform well in predicting mean flows when compared to historical observations, for~~  
530 ~~example Cohen et al. (2022), which show report an  $R^2$  of 0.99 in 30-year average prediction against USGS gauge~~  
531 ~~data and global river datasets (Cohen et al., 2022), it is important to acknowledge the uncertainties and limitations~~  
532 ~~in the both the precipitation data and model parameterisation and initial conditions, including the role of~~  
533 ~~anthropogenic impacts, which are greatly simplified in WBMsed. Many of the ~~s~~. In addition, u~~Uncertainties in  
534 ~~the precipitation input data, such as those derived from satellite-based precipitation datasets, including retrieval~~  
535 ~~errors, can propagate through the hydrological model, potentially affecting the accuracy of simulated discharge.~~  
536 ~~Additionally, g~~Globally calibrated model parameters may introduce further uncertainty, particularly in regions  
537 ~~with limited observational data coverage. Due to the limited availability of observed discharge in Africa and Asia,~~  
538 ~~evaluation predominantly focuses on North and South America and Europe. Hence, further evaluation in Africa~~  
539 ~~and Asia could be essential to enhance the robustness of global hydrological models.~~

540 Overall, the evaluation presented in this paper underlines the importance of selecting high-quality precipitation  
541 datasets to drive hydrological models. Since no single precipitation dataset was found to be adequately accurate  
542 everywhere, ~~across different temporal scales~~, this study can help identify the best precipitation products for any  
543 basin or region under consideration. Based on our results, MSWEP is the best overall choice but there are regions  
544 where ERA5, CHIRPS and CPCU were better overall ~~(e.g., see Figure 10)~~. All the precipitation datasets,  
545 particularly ERA5 and PERCCDR, require bias correction before being used to drive hydrological models in

546 regions like North America, Asia, Africa, and Australia. For data-scarce regions such as Africa and Asia, it is  
547 difficult to recommend a precipitation dataset due to the limited number of hydrological stations used **for**  
548 **validation** in this study. Finally, improving the precipitation datasets by adding more ground observations, for  
549 example, and by better representing anthropogenic drivers in hydrological models has the potential of  
550 considerably improving global and regional hydrological predictions.

#### 551 **Data availability**

552 The selected precipitation datasets used in this study are openly accessible to the public. ERA5 is freely available  
553 from the Copernicus Climate Data Store (CDS; <https://cds.climate.copernicus.eu/cdsapp#!/dataset/reanalysis-era5-land?tab=overview>). CHIRPS can be obtained from the Climate Hazards Group (CHG;  
554 <https://www.chc.ucsb.edu/data/chirps/>). Access to the MSWEP precipitation dataset is provided through the  
555 GloH2O website (<https://www.gloh2o.org/mswep/>). TERRA is accessible from the Climatology Lab website  
556 (<https://www.climatologylab.org/>). CPCU is publicly available through the NOAA Physical Sciences Laboratory  
557 (PSL; [https://downloads.psl.noaa.gov/Datasets/cpc\\_global\\_precip/](https://downloads.psl.noaa.gov/Datasets/cpc_global_precip/)), and PERCCDR can be freely accessed  
558 through the Center for Hydrometeorology and Remote Sensing (CHRS; <https://chrsdata.eng.uci.edu/>).

#### 560 **Author contribution**

561 SG, JL, and SJD conceived the study, incorporating input from all co-authors. SG led the global hydrological  
562 modelling, while JL, SJD, and LS assisted with data management and computational resources. SG was  
563 responsible for evaluating various precipitation datasets for hydrological modelling and drafted the initial  
564 manuscript. SC provided the hydrological model and input parameters. MW, GB, RB, PD, HG, EV, YL, RH, LH,  
565 SM, and JN executed extensive data quality control and identified stations for evaluation. PA, HC, AN, AT, and  
566 JS provided code, methods, and guidance. DP, SJD, and SED supervised the research and secured funding. All  
567 authors contributed to investigating research findings and played integral roles in manuscript writing and editing.

#### 568 **Competing interests**

569 We declare that Louise Slater is a topical editor of Hydrology and Earth System Sciences (HESS).

#### 570 **Acknowledgements**
