20
21 **Abstract:** Moraine-dammed glacial lakes are vital sources of freshwater but also pose a hazard to
22 mountain communities if they drain in sudden glacial lake outburst floods. Accurately measuring
23 the water storage of these lakes is crucial to ensure sustainable use and safeguard mountain
24 communities downstream. However, thousands of glacial lakes still lack a robust estimate of their
25 water storages because bathymetric surveys in remote regions are difficult and expensive. Here we
26 geometrically approximate the shape and depths of moraine-dammed lakes and provide a cost-
27 effective model to improve lake water storage estimation. Our model uses the outline and the terrain
28 surrounding a glacier lake as input data, assuming a parabolic lake bottom and constant hillslope
29 angles. We validate our model using ten new bathymetrically surveyed glacial lakes on the Qinghai-
30 Tibet Plateau, and compiled data from 34 recently measured lakes. Our model overcomes the
31 autocorrelation issue inherent in earlier area/depth-water storage relationships and incorporates an
32 automated calculation process based on the topography and geometrical parameters specific to
33 moraine-dammed lakes. Compared to other models, our model achieved the lowest average relative
34 error of approximately 14% when analyzing 44 observed data, surpassing the >44% average relative
35 error from alternative models. Finally, the model is used to calculate the water storage change of

36 moraine-dammed lakes in the past 30 years in High Mountain Asia. The model has been proven to
37 be robust and can be utilized to update the water storage of lake water for conducting further
38 management of glacial lakes with the potential for outburst floods in the world.

39 **1. Introduction**

40 Moraine-dammed glacial lakes (MDLs) trap meltwater from snow, ice and liquid precipitation
41 within basins behind dams at or near the termini of glaciers (Westoby et al., 2014; Yao et al., 2018;
42 Veh et al., 2019). As glaciers have been retreating in past decades in most mountain regions
43 worldwide, new MDLs have been forming, and existing ones have been growing in size and water
44 storage (Bolch et al., 2012; Carrivick and Tweed, 2013; Cook et al., 2018; Shugar et al., 2020; Zhang
45 et al., 2023). During the period from 1990 to 2018, High Mountain Asia witnessed a remarkable 52%
46 and 54% increase in the number and area of MDLs, respectively (Wang et al., 2020). Notably, the
47 Eastern Himalayas experienced the most significant growth, leading in both the number and area of
48 MDLs during this period. MDLs are vital water reservoirs for communities in glaciated high
49 mountains, but were also repeatedly sources for Glacial Lake Outburst Floods (GLOFs) (Westoby
50 et al., 2014; Wu et al., 2019; Gao et al., 2021; Fischer et al., 2021; Zheng et al., 2021a). According
51 to a report by Lützwow et al. (2023), a total of 630 GLOFs have been linked to MDLs occurring in
52 27 countries between 850 and 2022 CE. A recent study indicates that multiple GLOFs documented
53 from 1964 to 2022 have caused damage to infrastructure in High Mountain Asia (Nie et al., 2023).

54 MDLs are prone to sudden failure due to the instability of the dam structure, releasing parts of
55 the impounded water storage in catastrophic floods (Westoby et al., 2014; Zheng et al., 2021b).
56 MDLs can grow towards steep slopes, where debris or ice could fall into the lakes, causing the
57 barriers to overflow (Emmer et al., 2014; Carrivick and Tweed, 2013; Liu et al., 2020). Due to their
58 high altitude and potential energy, these flood waves can attain runout distances of many tens of
59 kilometers, transporting and entraining large amounts of sediments from moraines and riverbanks
60 (Westoby et al., 2014). Many GLOFs have transformed into debris flows and their coarse debris
61 rapidly filled hydropower reservoirs and further destroyed infrastructure along the flow path
62 (Westoby et al., 2014; Zheng et al., 2021b). For example, GLOFs descending from the mountains
63 with high kinetic energy have recently damaged transport and power infrastructure such as the
64 Upper Bhote Koshi hydropower plant, with a reconstruction cost of 57 million USD (United States
65 dollar) (Cook et al., 2018). Future flash floods are a potential threat to major new infrastructure, for

66 example, hundreds more hydropower projects (Nie et al., 2023). GLOFs may also undercut
67 hillslopes along mountain rivers, which may fail, impound river runoff, and form potentially
68 unstable lakes (Zheng et al., 2021a). Thus, MDLs have become a major glacier-related hazard in
69 high mountains, and will likely remain so as glaciers could lose more than a third of their mass by
70 the end of the 21st century (Rounce et al., 2023). Appraising the water storage of glacial lakes is
71 key to allowing for sustainable development along river channels originating in glaciated
72 headwaters (Yao et al., 2018; Harrison et al., 2021; Shugar et al., 2020; Liu et al., 2020).

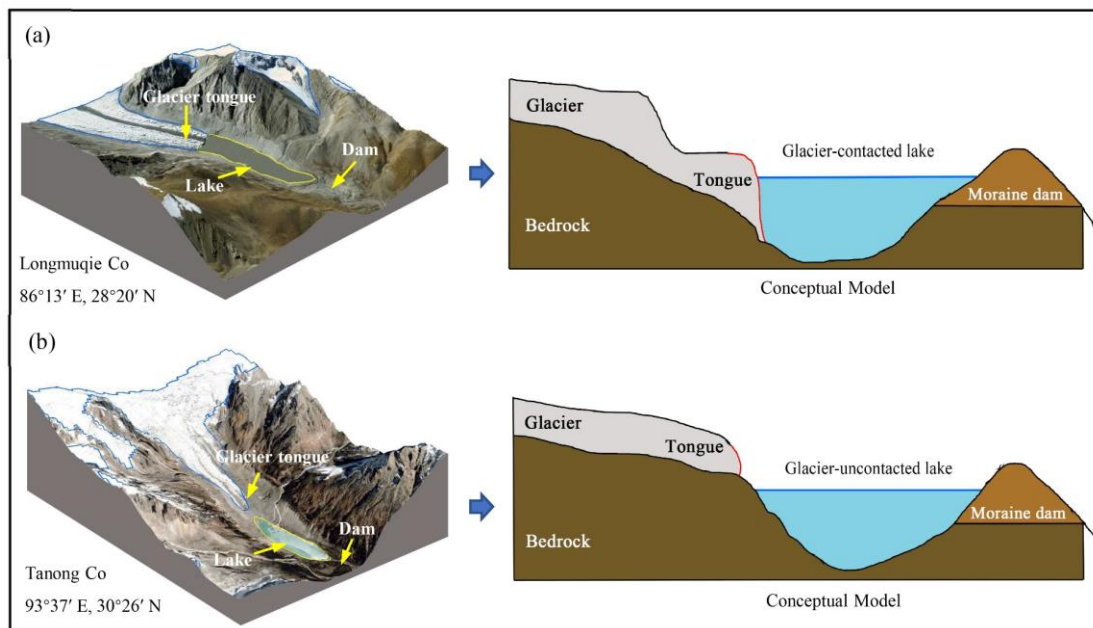

73 Effective management of GLOF hazards hinges on the ability to assess both the likelihood and
74 magnitude of such events (Clague et al., 2000). This typically requires understanding several critical
75 factors, including the water storage of MDL, the structural integrity and stability of the dam,
76 potential external triggers, and the flood's anticipated flow path (e.g., Richardson and Reynolds,
77 2000; Westoby et al., 2014; Mergili et al., 2020; Sattar et al., 2021; Qi et al., 2023). Estimating
78 glacial lake volume, however, presents significant challenges. Many glacial lakes are situated in
79 remote, physically demanding, and hazardous environments, complicating bathymetric surveys of
80 the lake basins (Cook and Quincey, 2015; Qi et al., 2022). Therefore, in situ measurements of lake
81 depth are available only for a few dozen cases in the Himalayas, while the water storage remains
82 unknown for the other thousands of lakes in this region. Current optical or radar-based satellite
83 missions, while useful for mapping lakes, are limited in measuring lake bathymetry due to the strong
84 attenuation of electromagnetic waves in glacial lakes (Zhu et al., 2019). As such, there has been an
85 ongoing effort to refine empirical scaling relationships from the few available worldwide samples
86 that relate glacial lake depth and/or area to lake water storage (Fujita et al., 2013; Loriaux and
87 Casassa, 2013; Carrivick and Quincey, 2014; Cook and Quincey, 2015; Veh et al., 2019; Shugar et
88 al., 2020; Qi et al., 2022). However, these equations may yield significant errors in orders of
89 magnitude for a given lake area due to the the autocorrelation issue inherent in earlier area/depth-
90 volume relationships. Although there are models considering the specific geometric shapes and
91 topography surrounding lakes, they limited to estimating the water storage of larger size plateau
92 tectonic lake (Zhou et al., 2020; Zhu et al., 2019). After numerous experiments, we have found that
93 the aforementioned models do not apply to estimating the water storage of glacier lakes due to the
94 lack of consideration for glacial lake and related parameters. Given the critical role of glacial lake
95 water storage in assessing hazard risk and providing early warning information, the development of

96 a mathematically robust yet cost-effective model is urgently needed.

97 Our goal is to introduce a novel approach for accurately estimating water storage by
98 incorporating its geometry and surrounding terrain. To this end, we propose a three-dimensional
99 model to approximate the basin morphology of MDLs and derive its analytical equation. We assess
100 the performance of this model against field-measured underwater topography data and further
101 compare the model error against other available empirical scaling relationships. Finally, we discuss
102 the uncertainty and rationality of the new model and apply the model to estimate the water storage
103 of the MDLs in High Mountain Asia.

104 2. MDLs types and their geometric approximation

105 MDLs can be classified into glacier-contacted lakes (GCL) and glacier-uncontacted lakes
106 (GUL). GCLs are supraglacial ponds on top of debris-covered glaciers or lakes at the termini of
107 glaciers (Richardson 2000; Bennett et al., 2012). We term GCL as MDL in direct contact with the
108 glacier terminus (Figure 1a). By contrast, GULs are separated from the present glaciers, but
109 impound substantial parts of the meltwater from the glacier upstream (Figure 1b). The bottom of an
110 MDL may be a sediment-covered bedrock depression that was eroded and deepened by the parent
111 glacier during earlier advances. As glaciers retreat, they provide space for lakes to grow between
112 the glacier terminus, with the abandoned moraine trapping excess meltwater from the parent glacier
113 (Nie et al., 2023).

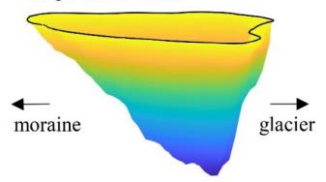

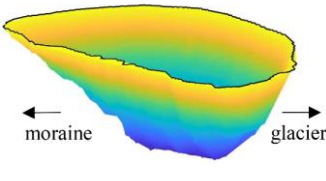

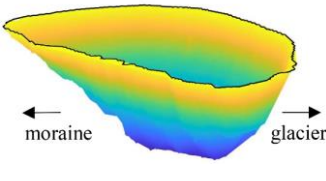

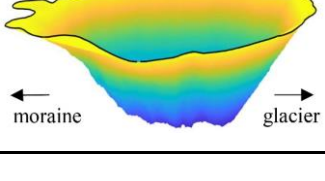

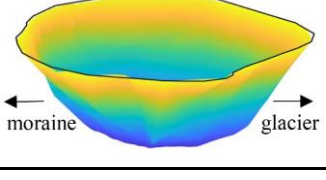

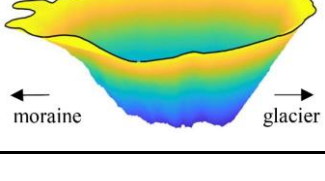

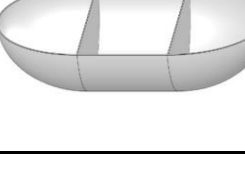

114
115 **Figure 1.** Longitudinal cross-sections along a glacier-contacted (a) and glacier-uncontacted lake (b) (The base

116 images are from Google Earth imagery) (©Google Earth). Sketches are idealized and do not represent measured
117 elevations.

118 We use the glacial lake inventory of High Mountain Asia by Wang et al. (2020) to differentiate
119 these two types of MDLs. In general, glacial lakes grow in area largely because they become longer.
120 Lower values of the ratio (R) between the maximum width and maximum length indicate that the
121 shape of the lake is elongated; R equals 1 if the lake is perfectly circular or square (Qi et al., 2022).
122 According to the glacial lake inventory, the R value for glacial lakes in High Mountain Asia ranges
123 from 0.1 to 1.0. If R is less than 0.1, it may indicate the presence of glacial lakes with lengths
124 exceeding 10 meters but widths of approximately 1 meter. However, in reality, glacial lakes with
125 such dimensions are practically non-existent. Therefore, thresholds of R allow us to distinguish
126 glacial lakes into four subclasses (Table 1). We find that newly formed GCLs typically have small
127 surface areas and high values of R . We classified GCLs with R between 0.70 ~ 1.0 as GCL-1, and
128 those with R less than 0.69 as GCL-2. Examples of these two types are Poiqu No.1 Lake (85.92°E,
129 28.14°N) and Bienong Co (93°26'E, 30°31'N) (Table 1). With ongoing glacier recession, lakes
130 might become decoupled from their parent glacier, switching from a lake-terminating to a land-
131 terminating glacier. We termed lakes as GUL-1, if R ranged between 0.5 and 1.0, and GUL-2 if $R <$
132 0.49. Paqu Co (86°15'E, 28°30'N) and Jialong Co in 2020 are the examples of these two classes
133 (Table 1). It is noteworthy that the establishment of the R threshold in this study is grounded in the
134 glacial lake catalog dataset developed by Wang et al, (2020). Initially, the glacial lakes were divided
135 into two major categories, GCL and GUL. Subsequently, R values for each glacial lake were
136 calculated, and all co-authors classified the geometric shapes based on different types and sizes of
137 glacial lakes. Ultimately, through statistical analysis of glacial lake sizes for different types, we
138 defined the threshold for R . This allows the model to automatically categorize glacial lakes based
139 on this value.

140 **Table 1** Examples of glacier-contacted lake and glacier-uncontacted lake. The ratio R represents the maximum width
141 (m) divided by the maximum length (m) of the glacial lake. The vertical scale is exaggerated.

Type	Lake bathymetry	Model	Features	R
------	-----------------	-------	----------	-----

GCL-1	<p>PoiquNo.1 of 2021</p> 		<p>A newly formed MDL typically has a small scale and is located at the glacier tongue.</p>	$0.70 \leq R \leq 1.0$
GCL-2	<p>Bienong Co of 2021</p> 		<p>The MDL gradually grows in the area but has not yet reached the maximum range determined by the surrounding terrain.</p>	$0.10 \leq R \leq 0.69$
GUL-1	<p>Paqu Co of 2020</p> 		<p>As the glacier continues to retreat, the distance between the glacier tongue and the MDL gradually increases.</p>	$0.50 \leq R \leq 1.0$
GUL-2	<p>Jialong Co of 2020</p> 		<p>The length of the MDL increases with time due to the continuous supply with glacier meltwater.</p>	$0.10 \leq R \leq 0.49$

142

143 3. Model Development

144 3.1. Input data

145 We suggest specific geometric models for the four subclasses (Table 1) to approximate the
 146 water storages of MDLs. Our models are fed with data from a digital elevation model (DEM) and
 147 from the outline of a glacial lake. We used a 12.5-meter ALOS PALSAR DEM, which is freely
 148 available from the Japan Aerospace Exploration Agency (JAXA, <https://www.eorc.jaxa.jp>).

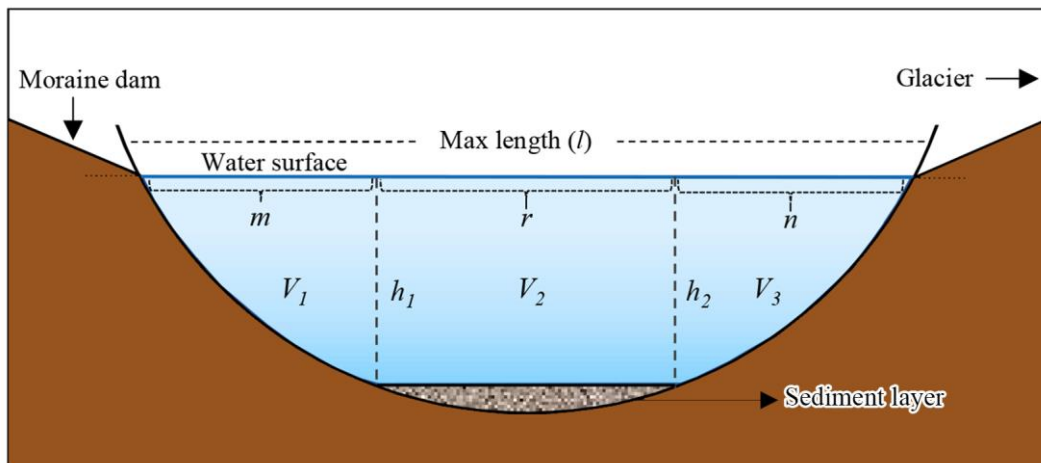

149 3.2. Analytical equations

150 We surmise that an ideal cross-section of a MDL (Figure 2) can be partitioned into three distinct
 151 portions, V_1 , V_2 , and V_3 , representing the water storage of the lake stored adjacent to the moraine
 152 dam, at the center of the lake, and near the glacier (or bedrock if the lake is disconnected from the
 153 glacier). The corresponding lengths of these three portions along the maximum length of the lake
 154 are denoted by m , r , and n . The lake has its maximum depth, h_1 and h_2 , on either side of r . Points g
 155 and f represent the positions of a sediment layer at the lake bottom, and a and β are the slopes of

156 near the water surface.

157 The core assumptions of our geometric model can be summarized such that: 1) an MDL has a
158 parabolic longitudinal bottom profile with a uniform sediment layer at the bottom of the lake to keep
159 $h_1 = h_2$, and a parabolic cross-section P_s (Figs. 2; 3); (2) the lake surface shape can be approximated
160 by ellipses at both ends and a rectangle in between; (3) The glacier surface and the moraine dam dip
161 towards the lake with the same slope.

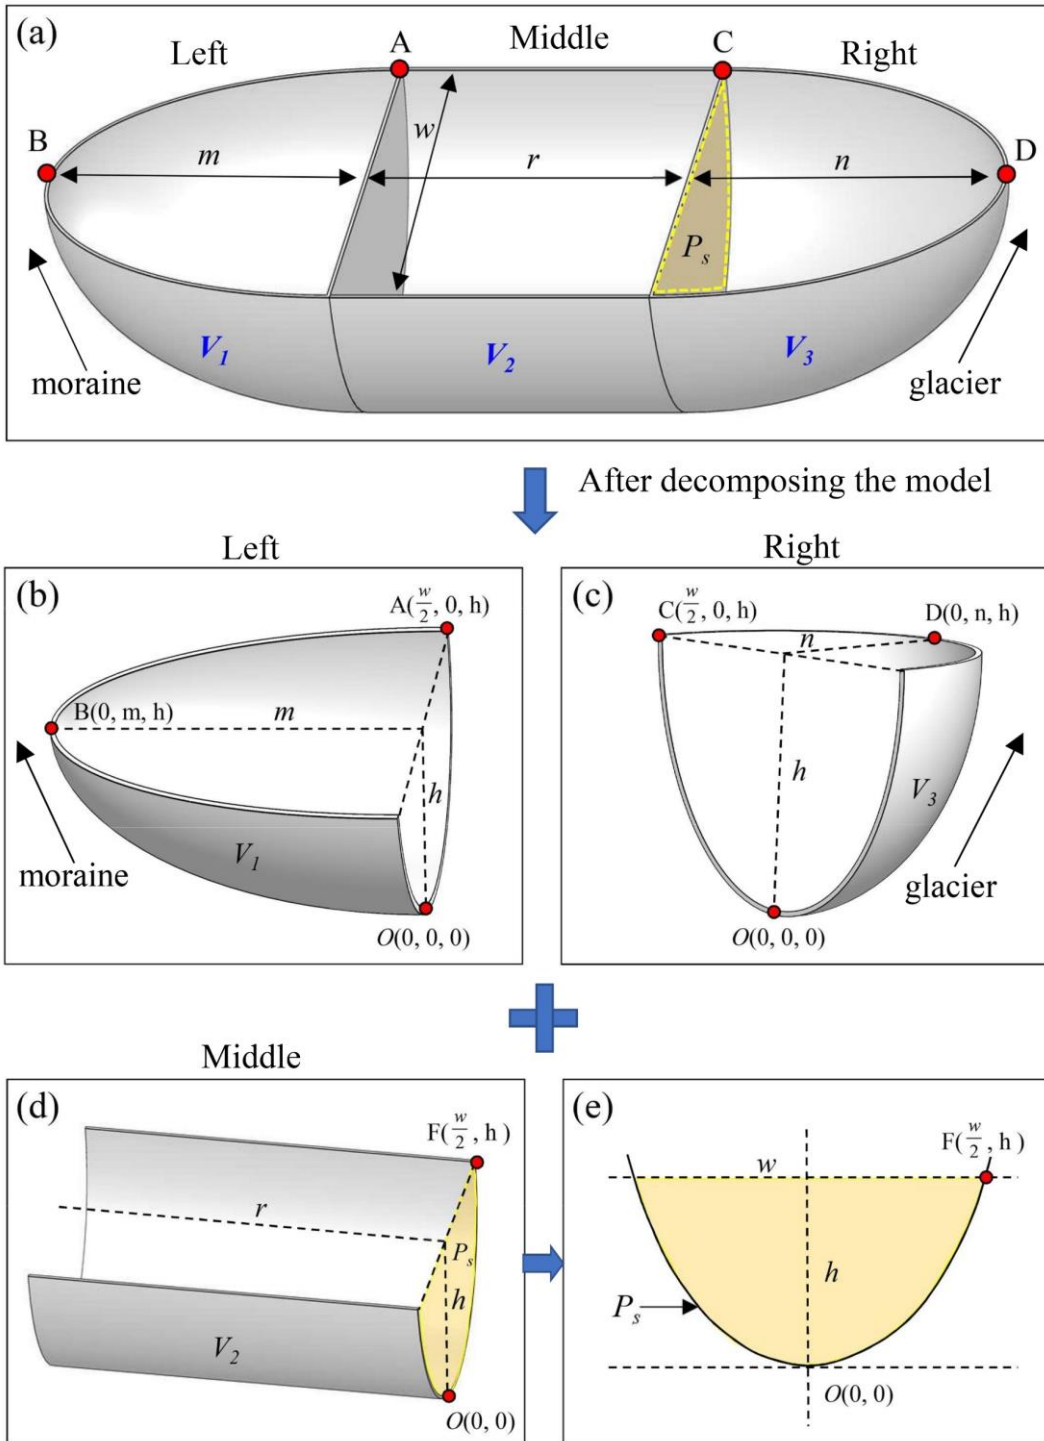

162

163

164 **Figure 2.** Longitudinal cross-section through a MDL. The blue horizontal line (l) is the maximum length on the lake
165 surface, subdivided by m , r , and n . The solid black line is the hypothetical bottom of the lake, and the gray texture
166 area represents a sediment layer covering the lake bottom. The maximum water depth is $h=h_1=h_2$, and points g and
167 f are at equal depths.

168 In three-dimensional form, the MDL basin can be divided into three parts with each having a
169 water storage of V_1 , V_2 , and V_3 (Figure 3a). V_1 and V_3 can be considered as the water storages of
170 elliptical semi-paraboloids controlled by the water depth h (Figure 3b and c). Significantly, V_1 and
171 V_3 may or may not be equal, depending on the values of m and n . V_2 is a semi-parabolic cylinder
172 (Figure 3d) that has height r , diameter w , and a parabolic cross-section P_s (Figure 3e). Thus, the total
173 water storage of the MDL is $V=V_1+V_2+V_3$.

174

175 **Figure 3.** Definition diagram for the geometry of a MDL. a, hypothetical three-dimensional model of a
 176 MDL. b, Model for V_1 describing the lake water storage adjacent to the moraine dam. c, Model for V_1
 177 describing the lake water storage adjacent to the glacier. d, Model for V_3 describing the lake water storage
 178 stored in the center part of the lake. e, Cross section of the column P_s . The parameters m and n are the
 179 semi-major axis of the elliptical paraboloid near the MDL inlet and outlet, respectively; r is the length of
 180 the parabolic cylinder in the middle of MDL; w and l represent the largest width and length of the MDL,
 181 respectively; h is the lake depth.

182

To obtain the individual lake water storages, we define the elliptical paraboloids for V_1 and V_2

183

(equations 1-2) in a Cartesian coordinate system (x, y, z) as

184
$$V_1 = \left\{ (x, y, z) \mid \frac{x^2}{a_1^2} + \frac{y^2}{b_1^2} \leq z, y \geq 0, 0 \leq z \leq h \right\} \quad (1)$$

185
$$V_3 = \left\{ (x, y, z) \mid \frac{x^2}{a_2^2} + \frac{y^2}{b_2^2} \leq z, y \geq 0, 0 \leq z \leq h \right\} \quad (2)$$

186 and the parabolic cylinder for V2 (equation 3) as

187
$$V_2 = \left\{ (x, y, z) \mid kx^2 \leq z \leq h, 0 \leq y \leq r \right\} \quad (3)$$

188 where $a_1 > 0, b_1 > 0, a_2 > 0, b_2 > 0$ are length of the semi-axes of upper surfaces of V_1 and V_3 ; $h >$
 189 0 is the height of V_1, V_2 and V_3 ; $r > 0$ is the length of V_2 .

190 Considering the four types of MDLs, GCL-1 corresponds to the case where $r=0$ and $n=0$. In
 191 this study, m represents the part of the lake area closer to the moraine dam, and in most cases, m
 192 not equal to zero. However, in certain special cases, such as the Lake Zhasuo Co (93.25°E, 30.31°N)
 193 in southeastern Tibet, $m=n=0$, because the surface morphology of this lake is rectangular. In most
 194 scenarios, the water storage of the GCL-1 can be represented as:

195
$$V_{\text{GCL1}} = \frac{\pi w m h}{8}. \quad (4)$$

196 When $n=0$, the model of MDL corresponds to GCL-2, and its water storage can be
 197 represented as

198
$$V_{\text{GCL2}} = \frac{\pi w m h}{8} + \frac{2}{3} w h r. \quad (5)$$

199 When $r=0$, the model of MDL conforms to GUL-1, and its water storage can be expressed as:

200
$$V_{\text{GUL1}} = \frac{\pi w h l}{4}. \quad (6)$$

201 When the type of MDL corresponds to GUL-2, its water storage can be expressed as:

202
$$V_{\text{GUL2}} = \frac{\pi w h (l - r)}{4} + \frac{2}{3} w h r. \quad (7)$$

203 Finally, the water depth (h) can be derived from the w and slope angles (α) of the glacial lake:

204
$$h = \frac{w \tan(\alpha)}{4}. \quad (8)$$

205 Section 1 in the Supplementary file elaborates more on the derivation of these analytical
 206 equations, Table 2 shows the definition of the abbreviations in the model procedure.

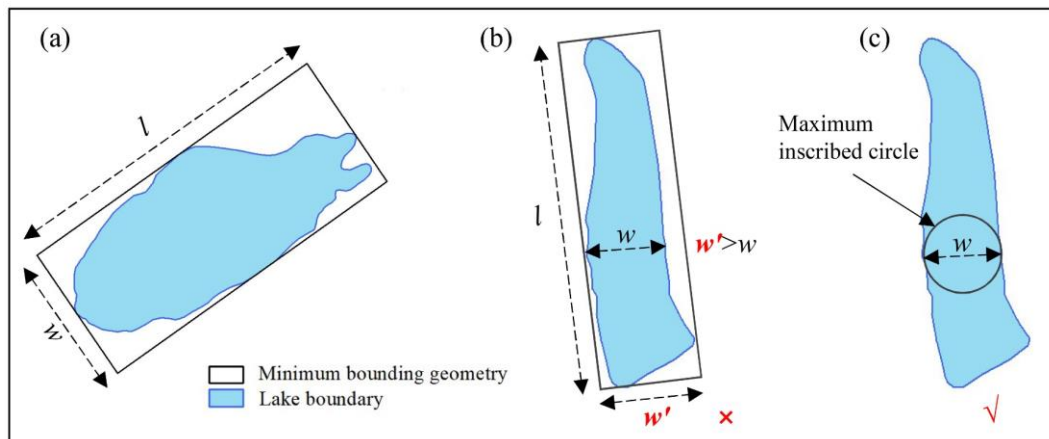

207 **Table 2.** The definition of the abbreviations in the geometric model.

Abbreviation	Description and definition
--------------	----------------------------

MDL	The moraine-dammed lake
GUL	The glacier-uncontacted lake
GCL	The glacier-contacted lake
R	The ratio of the maximum width to the maximum length of the MDL
m	The semi-major axis of the elliptical paraboloid of the MDL outlet
n	The semi-major axis of the elliptical paraboloid at the MDL inlet
c	The arbitrary height of the cross-section of an elliptic paraboloid
r	The length of the parabolic cylinder in the middle of MDL
h	The maximum water depth of MDL
w	The diameter of the largest inscribed circle of the MDL
l	The length of the minimum bounding rectangle of MDL
P_s	The cross-section of the middle of MDL
S_{P_s}	The area of the cross-section in the middle of MDL
a	The median slope of the 80 m buffer zone around the MDL

208 **3.3. Determination of model parameters**

209 We determined the parameters in Eq. 4 - 8, namely w , l , a , m , n and r , using the lake boundary
 210 and the DEM. We measured w and l by drawing a minimum rectangle bounding box with length l
 211 encompassing the MDL (Figure 4a). If the width w' of the bounding box of the MDL exceeds the
 212 actual width (w) of the lake, as in the case of the tortuous boundary of Lake Longmuqie Co (86.23°E,
 213 28.35°N) (Figure 4b), we assign the diameter of the maximum inscribed circle within the MDL as
 214 w in Figure 4c.

215

216 **Figure 4** Schematic illustration of the method for extracting the maximum length (l) and width (w) of the MDL. The

217 outline in Figure a represents the geometric boundary of Lake Jialong Co (86.85°E, 28.21°N), while the outlines in
218 Figures b and c depict the geometric boundaries of Lake Longmuqie Co (86.23°E, 28.35°N).

219 To determine the slope a -value surrounding the MDL, we use a DEM with a spatial resolution
220 of 12.5 m in the model computation. We tested buffer sizes of 30 m, 50 m, 80 m, and 100 m width
221 beyond the MDL boundary, and extracted the mean and median value of a within each buffer. By
222 comparing the simulated results with the measured data (lakes Bienong Co, Maqiong Co, Tanong
223 Co, and Jialong Co), we found that the water storage estimation using the median value of a within
224 80 m external buffer zone had a lower relative error and higher overall accuracy. Therefore, we
225 defined a -value as the median slope within the 80 m buffer zone surrounding the MDL boundary.
226 The choice of buffer zone distance can be adjusted based on the specific terrain characteristics of
227 the research area, allowing researchers to adapt the methodology to their data accuracy.

228 Determining the appropriate thresholds for m , n , and r of different MDL types is challenging
229 as methods for extracting these parameters vary depending on the MDL types. In other words, due
230 to the different types of glacial lakes, the values of m , n , and r vary. Additionally, these values change
231 with the size of the glacial lake. To enable the model to automatically identify and calculate the
232 corresponding m , n , and r for each glacial lake, we need to define a threshold. Based on the geometry
233 of the glacial lake, we established a proportional relationship between m , n , r , and the glacier lake
234 length (l). This proportional relationship is empirically defined and essentially represents a
235 geometric segmentation of the glacial lake. The lake is divided into three sections, and the volume
236 of each section is calculated separately. The total water storage of the lake is then obtained by
237 summing the volumes of these three sections. Relying on R , lake boundary from Wang et al. (2020)
238 as well as DEM, m and n were estimated for GUL-1 and GUL-2 as shown in Table 3. In the case of
239 GCL-1, $l = m$ due to its small area of water surface. For GCL-2, m was determined as 35% of l for
240 lakes with $0.50 < R < 0.69$, 30% of l for lakes with $0.30 < R < 0.49$ and 20% of l for lakes with $R < 0.30$
241 (Table 3).

242 For GUL-1, R ranges from 0.50 to 0.10, both m and n are considered equal to half of l . On the
243 other hand, for GUL-2, it is possible to estimate the MDL water storage solely based on r , as
244 described in Equation 7. Accordingly, r values were statistically set up as $0.4l$, $0.55l$, and $0.65l$,
245 respectively with three R levels (Table 3). Figure 5 illustrates several representative cases of MDLs.

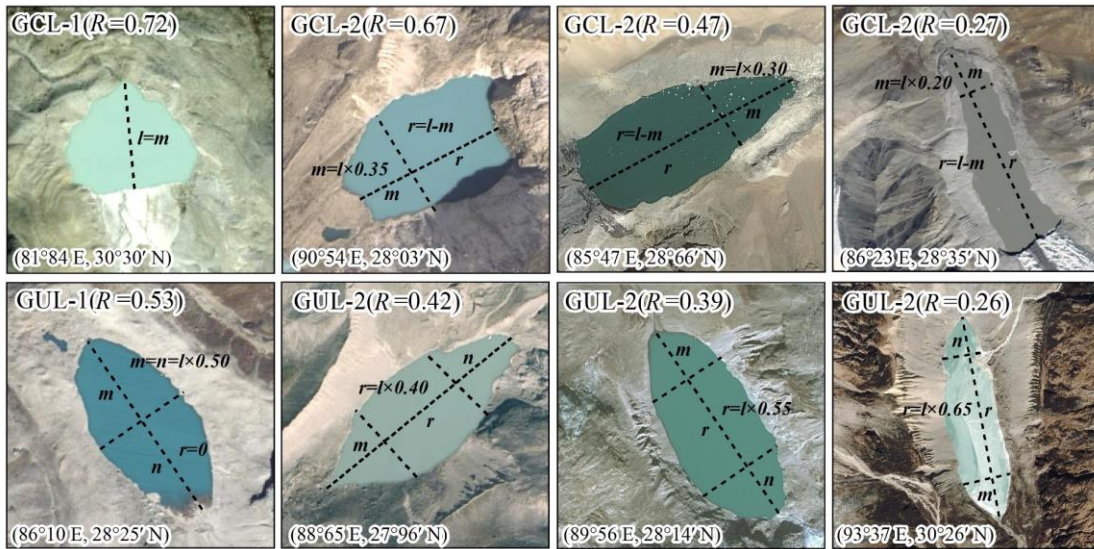

246 The above quantitative question about m , n and r is not based on subjective judgment. First,

247 we computed the R values for all glacial lakes utilizing catalog data, then categorized them by glacial
 248 lake type, and finally, we provided a definition by statistically assessing the shape of glacial lakes.
 249 This definition pertains to the proportionality of m , n , and r concerning the l of the glacial lake.
 250 Consequently, our model is capable of autonomously classifying each glacial lake type through
 251 boundary data analysis. It further computes various parameters for each lake, encompassing m , n , r ,
 252 and h , ultimately culminating in the determination of the water storage for each lake.

253 **Table 3** Quantification of model input parameters.

Lake type	Calculation rules of model input parameters					
	a	w, l	R	m	n	r
GCL-1			$0.70 \leq R \leq 1.0$	l	0	0
GCL-2	Median slope within the 80 m buffer zone	w is the diameter of the largest inscribed circle and l is the maximum	$0.50 \leq R \leq 0.69$	$l \times 0.35$	0	$l - m$
			$0.10 \leq R \leq 0.29$	$l \times 0.20$	0	$l - m$
GUL-1	outside the lake boundary	length of the minimum bounding geometry	$0.50 \leq R \leq 1.0$	$l \times 0.50$	$l \times 0.50$	0
GUL-2			$0.40 \leq R \leq 0.49$			$l \times 0.40$
			$0.30 \leq R \leq 0.39$	$l - r$		$l \times 0.55$
			$0.10 \leq R \leq 0.29$			$l \times 0.65$

254

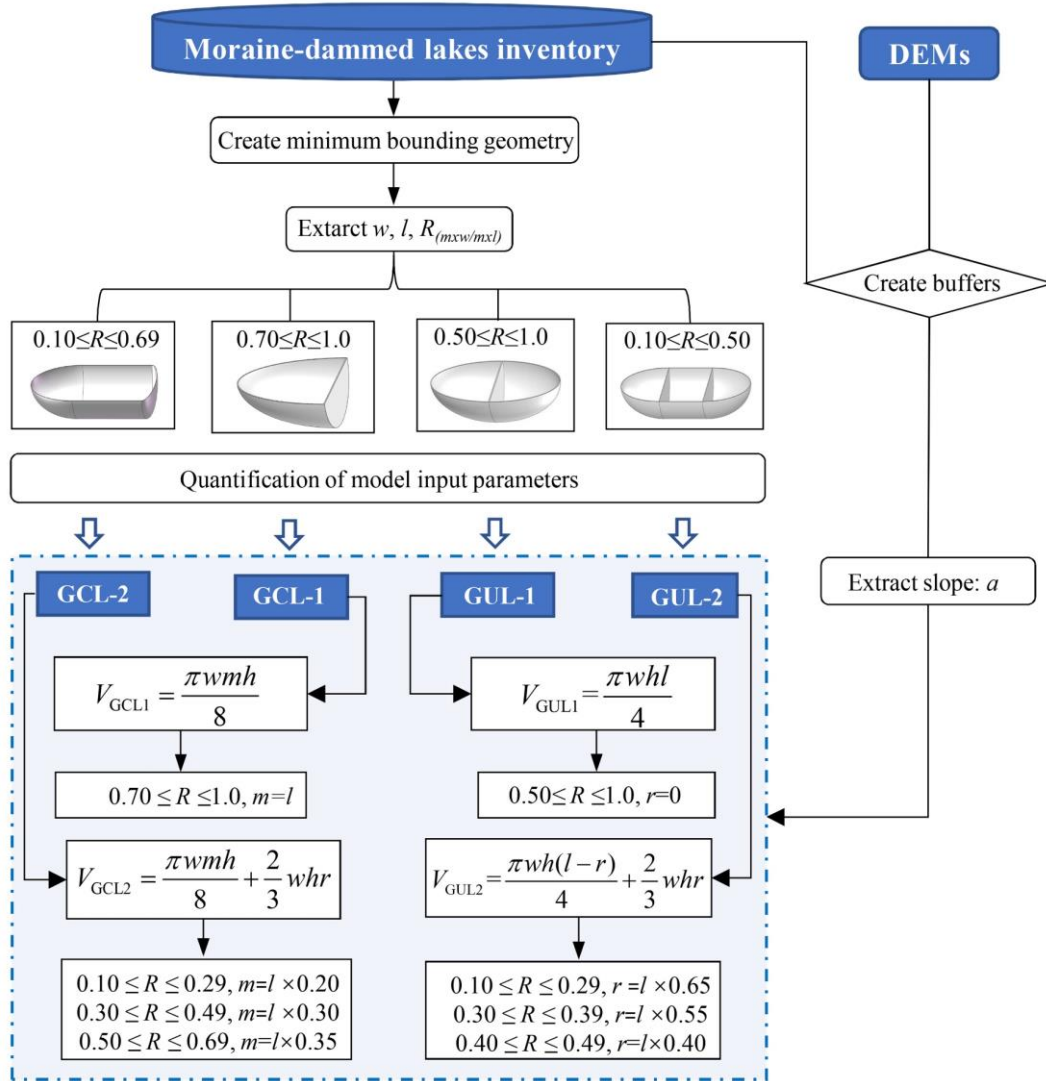

255

256 **Figure 5.** Example for the extraction of input parameters for different types of MDLs. The base map is a Google
 257 Earth image (©Google Earth).

258 We executed our workflow (Figure 6) on 44 MDLs in High Mountain Asia that have known
 259 depths and water storages. For each lake, we checked whether its outline was in contact to the parent
 260 glacier. We automatically fitted a rectangular bounding box to calculate R , and then automatically
 261 assigned each lake to one of the four types of MDL based on R thresholds (Table 1). Finally, we

262 estimated their water storages using our and traditional empirical relationships. Our model requires
 263 MDL boundary and DEM data as inputs, and it automatically quantifies each parameter while
 264 selecting the optimal model for water storage estimation.

265 Finally, we applied our model to more than 10,000 glacial lakes with unknown bathymetry in
 266 High Mountain Asia. This region had one of the highest rates of MDLs growth in the world in past
 267 decades.

268
 269 **Figure 6.** The flow chart of the model procedure derivation.

270 3.4. Model validation and application

271 In this study, we initially validated our parameterization using bathymetric measurements from
 272 four representative glacial lakes surveyed between 2020 and 2021. Subsequently, we combined the
 273 data from these four lakes with the remaining six glacier lakes we measured, along with water
 274 storage data from 34 MDLs obtained from relevant literature sources (see Appendix A for details).

275 This resulted in a dataset of 44 lakes, which was used to compare and validate the performance of
276 our model against other existing methods.

277 A glacier lake inventory of the High Mountain Asia region, published by Wang et al, 2020 was
278 used as input data for the model application to assess the water storage of moraine-dammed lakes
279 in this region. Notably, Wang's glacier lake inventory provides a detailed classification of GCL and
280 GUL, which has been internationally recognized. It is important to note that in his dataset, GUL
281 refers specifically to glacier lakes that do not contact glaciers, which may not necessarily all be
282 moraine-dammed lakes. To ensure the accuracy of our analysis, we conducted a thorough review
283 based on the classification criteria proposed by Yao et al., (2018) which identify three types of
284 moraine-dammed lakes: (1) lakes situated between the end moraine ridge and the glacier terminus,
285 (2) lakes beside the lateral moraine ridge, and (3) lakes on the moraine ridge. Each GUL in the
286 dataset was individually assessed against these criteria, and only those meeting the classification as
287 moraine-dammed lakes were retained for further analysis.

288 **4. Results**

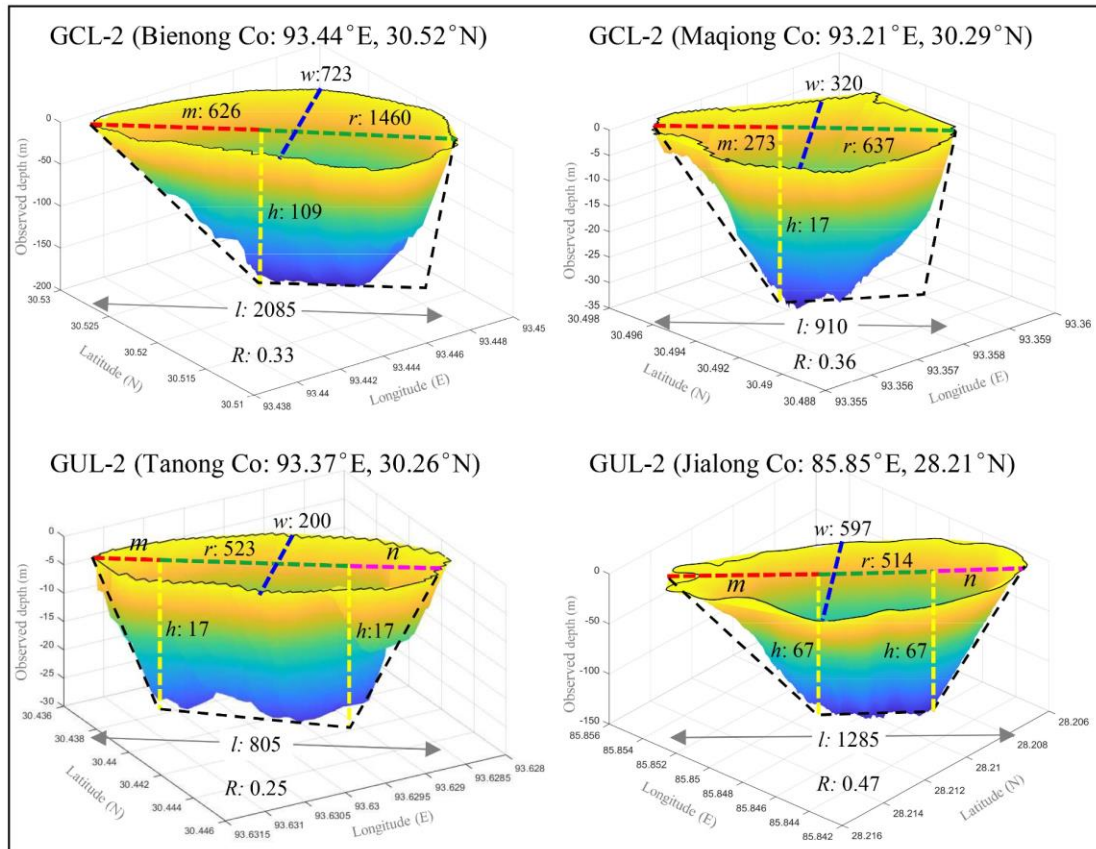

289 **4.1. Model validation**

290 We validated our parameterization using bathymetry measurements from four representative
291 glacial lakes, namely, Bienong Co, Maqiong Co, Tanong Co, and Jialong Co, located in the Qinghai-
292 Tibet Plateau. These lakes represent the four types of glacier lakes, with depths measured through
293 bathymetric surveying (Figure 7). In comparing estimated with measured water storages (Table 4),
294 we find that Jialong Co has the highest accuracy with a relative error of only 1%. Maqiong Co and
295 Tanong Co are overestimated by approximately 5% and 7%, respectively. The largest lake, Bienong
296 Co, had an underestimated water storage of 6%.

297 In addition, our model is designed to approximate the mean depth of MDLs and therefore
298 underestimates the maximum measured lake depth by about 50% (Table 4). Modeled mean water
299 depths only deviate by 18% (mean) from the measured mean water depths. Except for a notable
300 prediction error for Bienong Co (+47%), errors for Jialong Co, Tanong Co, and Maqiong Co range
301 from 6% to 13% relative to the measured values.

302 In summary, our model has a high degree of concordance with observed glacial lake water
303 storages and provides better estimations of water depth compared to the measured average depths.
304 This suggests that our proposed model can be used in glacial lake water storage estimation and the

305 management of GLOF hazards.

306
 307 **Figure 7.** Subaqueous glacial lake morphology based on bathymetric surveys. The black dashed line represents the
 308 hypothetical longitudinal profile of the glacial lake; l and w are measured from the lake boundary, h is simulated
 309 lake depth and the remaining parameters (m , n , r) are calculated by rule in Table 3. Lake depth is exaggerated.

310 **Table 4** Validation results of the mathematical model.

Name	Year of survey	Type	Area (km ²)	Lake depth (m)			Water storage (10 ⁶ m ³)		
				Observed (max/mean)	Simulated (mean)	Relative error	Observed	Simulated	Error
Bienong Co	2021	GCL2	1.16	181/74	109	+47%	102.00	95.689	-6%
Maqiong Co	2021	GCL2	0.22	34/16	17	+6%	3.325	3.581	+7%
Tanong Co	2021	GUL2	0.13	29/15	17	+13%	1.821	1.915	+5%
Jialong Co	2020	GUL2	0.55	135/62	67	+8%	37.530	37.952	+1%

311
 312 **4.2. Comparison with other methods**

313 Table 5 displays the dataset of glacial lake bathymetry used in this study to validate the model.
 314 We compared our model with another model that employed the lake geometry (Zhou et al., 2020),
 315 and also with 20 additional formulas (EqS1-EqS20) collated by Qi et al. (2022) in Table S1. In the
 316 estimation of a single MDL, formulas EqS4, EqS6, EqS13, EqS17, and EqS20 displayed significant

317 inaccuracies (132% - 853%). For instance, EqS13 shows an average error of 853%. Consequently,
 318 we have refrained from conducting a comparative analysis of these five formulas in the subsequent
 319 discussions.

320 **Table 5** The glacial lake bathymetry data set used in this study. The lake bathymetry data are shown in bold provided
 321 by this study, and the rest are obtained from references, see Appendix A for details.

322 Our assessment (Table 6) involves the relative error (RE, absolute value), bias, root mean
323 square error (RMSE), mean absolute percentage error (MAPE) and mean absolute error (MAE) to
324 quantify the uncertainty of new model. We use the coefficient of determination R^2 to describe the
325 goodness of fit between the model-derived data series and the measured data. Accordingly, our
326 model had an R^2 value of approximately 0.98, indicating a strong correlation between observed and
327 predicted lake water storages (Figure 8). Moreover, our model has the lowest variance, according
328 to a bias (-0.0031 km³), MAE (0.0059 km³), RMSE (0.0096 km³), and MAPE(25%). Also, our
329 model has the lowest average relative error, at around 14%. The average relative error of EqS2,
330 EqS3, EqS5, EqS7, EqS9, EqS11, EqS15 and EqS16 ranged from 44% to 50%, while the remaining
331 formulas display average relative errors exceeding 50%. Although all equations achieved $R^2 > 0.93$,
332 the predicted values have a high variance and tend to either overestimate or underestimate the water
333 storage of glacial lakes. Compared with our method, their bias, MAE, RMSE, and MAPE were all
334 55%, 64%, 52% and 64%, respectively, and thus higher than ours. EqS7 had a better prediction
335 accuracy. However, its bias, MAE and RMSE values are 82%, 64% and 52% higher than those of
336 our model, respectively. This indicates a significant estimation error for specific glacial lakes, and
337 both RMSE and MAE are sensitive to outliers. Overall, most of the equations tend to underestimate
338 glacial lake water storages, with the underestimation becoming more pronounced for larger water
339 storages. Nevertheless, we consider the accuracy level of our method to be acceptable due to the
340 lower uncertainty compared to other models, providing an alternative for predicting the water
341 storage of MDLs.

342

343 **Figure 8.** Comparison of the overall performance in glacial lake water storage estimation between our and

344 previous models (a) and comparison of measured and estimated water storage by our model (b).

345

346 **Table 6** Comparison of all empirical scaling relationships (EqS1-EqS20) in terms of bias, mean absolute error (MAE)

347 and root mean square error (RMSE) are measured in cubic kilometers. See Appendix B for details.

348 **4.3. Application of the new model**

349 Considering the frequent occurrence of GLOF events in High Mountain Asia, posing threats to
 350 downstream infrastructure and the safety of the lives and properties of the local communities,
 351 assessing the water storage of glacial lakes is crucial for management potentially hazardous ones
 352 (Nie et al., 2023). Therefore, this study employs our model to provide preliminary estimates of
 353 glacial lake water storages in the study area.

354 A glacial lake inventory data (Wang et al., 2020) reveals that in 2018, there were a total of
 355 13,166 glacial lakes ($\geq 0.01 \text{ km}^2$) distributed in High Mountain Asia. The dataset highlights a
 356 significant increase in both the number and area of GCLs from 1990 to 2018, experiencing a
 357 remarkable growth of 52% and 54%, respectively. Model estimation results indicate that the total
 358 glacial lake water storage in the study area was 37.18 km^3 in 2018. Over the past three decades, the
 359 overall MDL's water storage increased by 8.94 km^3 from 28.24 km^3 in 1990, representing a growth
 360 of approximately 32%. The expansion rates of glacial lakes varied significantly across different
 361 regions (Figure 9). Notably, the Hindu Kush-Karakoram and the central and eastern of the
 362 Himalayas to the Hengduan Mountains witnessed the fastest increases in both glacial lake area and
 363 water storage.

364

365 **Figure 9** Changes in the area and water storage of glacial lakes from 1990 to 2018 in High Mountain Asia. The base

366 map is a Google Earth image (©Google Earth).

367 The Eastern Himalayas had the largest gain in both the area and water storage of glacial lakes,
368 concurrently establishing it as a hotspot for frequent GLOFs (Figure 9). The results indicate that the
369 water storage of 1,410 MDLs ($\geq 0.01 \text{ km}^2$) within the study area was $9,337 \pm 990 \times 10^6 \text{ m}^3$ in 2022.
370 Among these, GCLs and GULs account for 70% and 30% of the total water storage, respectively.
371 Between 1990 and 2022, the total water storage in glacial lakes representing a substantial growth of
372 162%. Notably, GCLs contributed 134% with an average annual growth rate of $8.8\% \text{ a}^{-1}$, indicating
373 an overall increase of 280%. In contrast, the change in the water storage of unconnected lakes
374 remained relatively stable, experiencing a modest growth of 52% over the past 32 years,
375 considerably lower than that of GCLs.

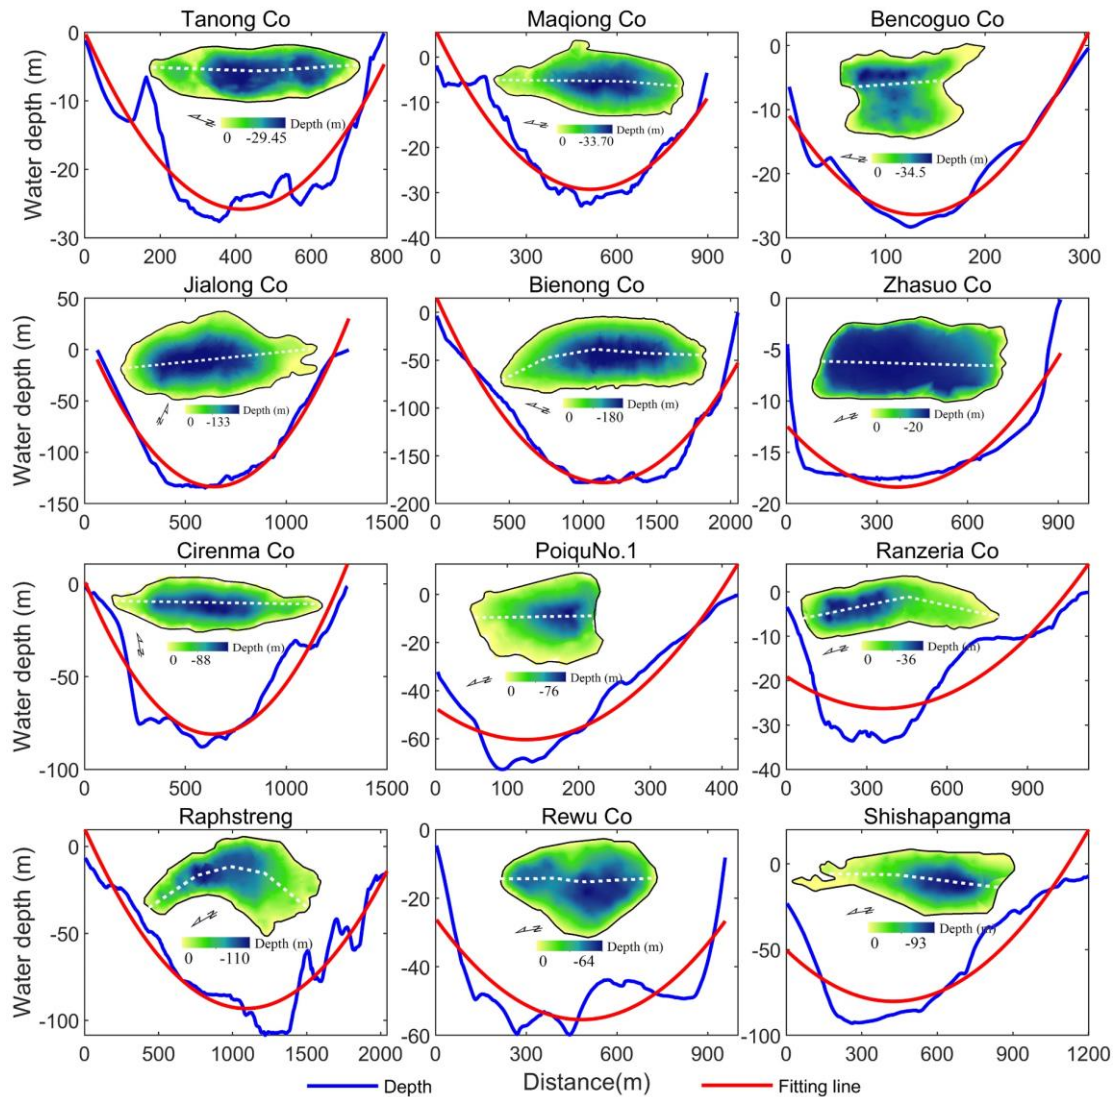

376 **5. Discussion**

377 **5.1 Justification and uncertainty of model assumptions**

378 In this study, we discuss the rationality and uncertainty of the model from three aspects. We
379 first assumed that the MDL features a parabolic longitudinal bottom profile and a uniformly
380 distributed sediment layer. The basin morphology of glacial lakes is a result of glacial erosion during
381 the glacier retreat process. Glacier erosion involves certain lateral shear stress, leading to the
382 formation of U-shaped valleys. Glacial lakes develop on these U-shaped valley terrains (Seddik et
383 al., 2009). Therefore, based on the lake bathymetry and the longitudinal bottom profile of the MDLs
384 (Figure 10), the variations in the underwater morphology of MDLs can be fitted with a parabolic
385 curve. However, when observing trends in underwater topography, it is evident that some large and
386 deep lakes (depth $> 100 \text{ m}$), such as Jialong Co and Bienong Co, exhibit relatively flat underwater
387 terrain, while others do not (Figure 7). This finding aligns with the research conducted by Carrivick
388 and Tweed (2013), who proposed that most proglacial lake basins have flat landforms resulting from
389 extensive sedimentation. These flat terrains, which were previously subdued and smoothed by
390 glaciation, can become covered and obscured by thin layers of silts and clays. Furthermore, it has
391 been suggested by some scholars that in large and deep proglacial lakes, the instability of the glacier
392 margin and the increased likelihood of wave erosion can lead to the erosion of moraine ridges at the
393 lake bottom (Murton et al., 2012).

394 The underwater landforms of some MDLs are not always a smooth parabolic shape. As
395 depicted in Figure 11, the bottom topography of most glacial lakes exhibits a fluctuating parabolic

396 trend. Golledge (2008) and Bennett et al. (2000) revealed that subaqueous moraines in glacial lakes
 397 often have linear or sinuous crests, and their ridges frequently exhibit heavily glactectonized
 398 sediment structures indicative of compression. Although the presence of subaqueous moraines is
 399 uncertain, this perspective offers a plausible explanation for the fluctuations in underwater
 400 topography. In conclusion, concerning the formation process of subglacial geomorphology in MDLs
 401 and lake bathymetry, both aspects substantiate our postulation that the MDL features a parabolic
 402 longitudinal bottom profile. Furthermore, we hypothesize the presence of uniform sediment surface
 403 to keep $h_1 = h_2$, although sediment distribution may be non-uniform due to factors such as the
 404 position of the ice margin and water density (Carrivick and Tweed, 2013). As a result, the uneven
 405 terrain at the bottom of some glacial lakes or the non-uniform distribution of sediments therein
 406 constitutes one of the sources of uncertainty in the model.

407
 408 **Figure 10.** The longitudinal bottom profile underwater topography of the MDLs obtained by bathymetry and the

409 fitting lines of terrain change trend (The white dotted line is the longitudinal profile line of the lake).

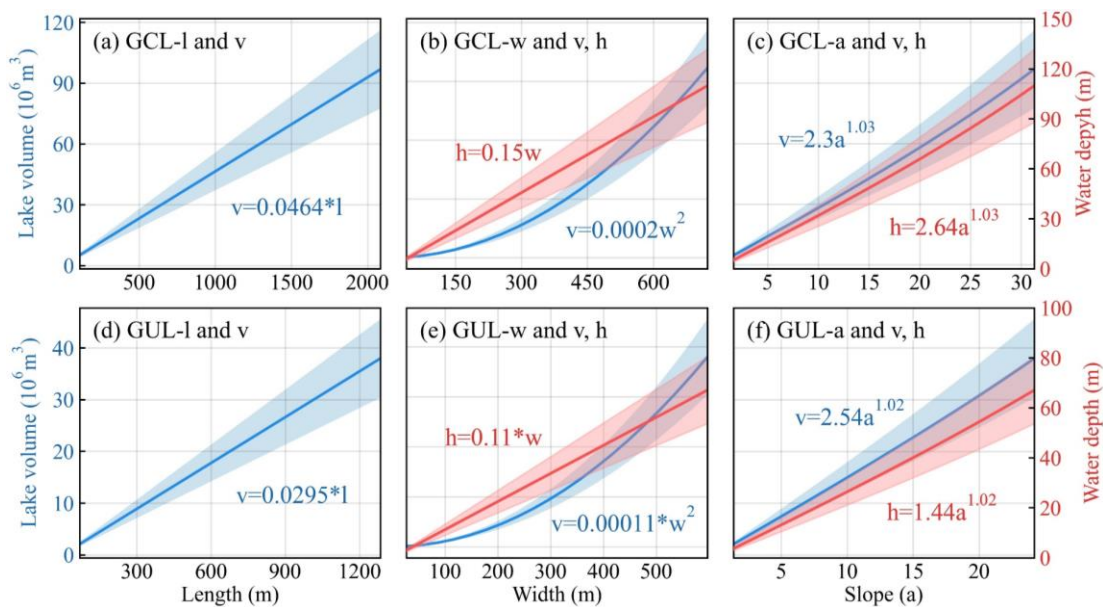

410 The second source of uncertainty in the model arises from the assumption regarding the lake
411 surface of the MDL. Here, we assumed MDL's surface shape is characterized by an ellipse at both
412 ends and a rectangle in between. MDLs develop on parabolic or U-shaped glacial troughs. A mature
413 MDL, characterized by a relatively stable surface morphology, tends to exhibit an elliptical shape
414 due to its geological characteristics (e.g., GUL lake type in Figure 5). Similar trends in the
415 boundaries of MDLs are observed in different lake catalog datasets. Furthermore, in this study,
416 MDLs are classified into four types based on their geometric shapes (see Table 1). Treating the
417 complete geometric shape of an MDL as an ellipse allows the model to automatically partition the
418 lake basin structure (e.g., V_1 , V_2 , V_3 in Figure 2) based on the lake's shape coefficient, facilitating
419 the calculation of the water storage for MDLs with different morphologies. However, in reality, as
420 suggested by Teller (1987) and Rubensdotter et al. (2009), factors such as the position of the glacier
421 margin, surrounding landscape elevation and topography, and the location and elevation of lake
422 overflow channels can affect the basin morphology of MDLs. For instance, Bencoguo Co and
423 Raphstreng in Figure 10 do not exhibit the characteristic elliptical shape on the lake surface. This
424 uncertainty in the geometric shape of the lakes may lead to an overestimation of lake water storage
425 in the model, as the maximum width of the lake significantly influences the model results.

426 Finally, assuming the slope angle near the lake remains constant ($\alpha=\beta$) is another aspect
427 contributing to the uncertainty in the model. In actuality, the slopes surrounding the lake exhibit
428 variations influenced by factors like the glacier tongue's position, the surrounding topography, and
429 the presence of moraine ridges. This variability in slope angles can further contribute to the
430 uncertainty when estimating the model's maximum water depth and water storage.

431 **5.2 Sensitivity of model input parameters**

432 Additionally, our model requires key parameters, namely, w , l , a , m , n , and r , with the
433 relationship between m , n , r , and l defined as $l = m + n + r$. Thus, we only investigated the sensitivity
434 of our model to l , w , and a . Since water depth is closely related to w and a (see equation (13)), we
435 also conducted parameter sensitivity tests on the estimated water depth using our model. In this
436 study, we employed Jialong Co and Bienong Co as representatives of GUL and GCL of MDLs,
437 respectively, to assess the sensitivity of the model to various parameters across different types of
438 glacial lakes. Figure 11 (a-f) demonstrates the sensitivity of volume (v) and water depth (h) in our

439 model to variations in the maximum length (l), maximum width (w), and slope (a) of glacial lakes.
 440 Overall, there was a linear increase in glacial lake volume with changes in length (Figures 11a and
 441 d). As shown in Figures 11b and e, variations in maximum width exhibited a consistent power-law
 442 relationship with volume, where volume increased exponentially with width. The water depth of
 443 glacial lakes demonstrated a linear increase with changes in width. The slope of the lake's edge
 444 showed a power-law relationship with both estimated water depth and volume (Figures 11e and f).
 445 In summary, when estimating volume using our model, glacial lake width and slope were found to
 446 be the most sensitive parameters, followed by the lake's length. Regarding water depth, the model
 447 was most sensitive to the slope, followed by the width.

448
 449 **Figure 11.** Parameter sensitivity analysis for glacial lake volume estimation using new model (note: the shaded
 450 part represents the confidence interval, and definition of parameters in the figure as shown in Table 2).

451 6. Conclusion

452 Water storage plays a crucial role in predicting peak discharge of GLOFs. This study proposed
 453 a mathematically robust and cost-effective approach for estimating lake water storage in regions
 454 where field measurements of bathymetry are limited. The new model utilized lake geometry and
 455 DEMs to estimate lake water storage. By parameterizing the model based on assumptions such as a
 456 parabolic longitudinal bottom profile and consistent slope angles, it offers a reliable estimation of
 457 lake water storage.

458 We validated our parameterization using bathymetry measurements from four representative
 459 glacial lakes, namely, Bienong Co, Maqiong Co, Tanong Co, and Jialong Co, located in the Qinghai-

460 Tibet Plateau. Additionally, we applied the new model to 10 glacial lakes with depth measurements
461 conducted during 2020-2021, and we included bathymetry data from 34 other glacial lakes sourced
462 from published literature. Our model overcomes the autocorrelation issue inherent in earlier
463 area/depth-water storage relationships and incorporates an automated calculation process based on
464 the topography and geometrical parameters specific to MDLs. Compared to other models, our model
465 achieved the lowest average relative error of approximately 14% when analyzing 44 observed data,
466 surpassing the >44% average relative error from alternative models. This study model will allow
467 researchers and practitioners to better predict potential outburst water storages and peak discharge
468 of MDLs.
